The absence of effective institutional checks on the power of the ruler charged with achieving sociopolitical order on a macro level mirrored the absence of procedural constraints of the Confucian literati charged with resolving conflict on an interpersonal level. The combination of the lack of effective restraints and the elitist fallacy - that the Confucian literati/sage/ruler possessed superior normative insights - left the disempowered largely at the mercy of

those in power.

3 The evolution of *li*: increased codification and stratification

The hierarchical nature of society was further reinforced by the *li*, which reflected differences in personal cultivation and social accomplishment and in so doing inevitably fostered such differentiation. Confucius maintained that humans are by nature similar. Each person has the potential to become a sage. At the same time, however, he realized that not all people will become sages. As a practical matter, people will achieve different levels of cultivation and accomplishment. A properly functioning society recognizes excellence and harmoniously integrates the varying roles of its members. Thus it was essential for Confucius that each person fulfilled their role, as delineated by the *li*: a ruler was to act as a ruler, a minister as a minister, a father as a father, a son as a son, a friend as a friend and so on.

To be sure, neither one's role nor the rules (*li*) delineating one's role were predetermined for Confucius. One could escape one's class through personal cultivation. Indeed, as one moved through life, one's role naturally changed. First a son, one later becomes the father; first the subordinate, one later assumes positions of increasing authority. Further, as noted above, Confucius insisted that the *li* required personal investment, interpretation and adaptation, lest they become ossified and outdated rules of petty etiquette.

Confucius' words, however, were not heeded. Over time, the *li* became increasingly codified and rigid. One finds in many classic texts, the *Liji (Book of Rites)*, the *Xunzi*, even in the *Analects* of Confucius, painstakingly detailed expositions of the proper behaviour for the various strata: the ruler was to use a *jian* cup, the ministers a *jia* cup; a ruler used a decorated bow, a feudal lord a red bow, a high officer a black bow, and so on. More important than the exhaustive detail of these works, however, is the underlying theory. There is a marked change in emphasis from Confucius' own view of the *li* as flexible and adaptable and of society as a continually evolving, open-ended project. Increasingly, the primary function of the *li* is taken to be class differentiation. Thus we find the Confucian Xunzi asserting:

> The ancient kings invented the *li* and standards of rightness (*yi*) for humans in order to divide them; causing them to have the classes of noble and base, the disparity between elderly and young, the distinction between wise and stupid, the able and the incompetent; all to cause people to assume their duties and each to get his proper position.
>
> (*Xunzi*)

Similar sentiments were echoed in a wide variety of classical texts, from the *Liji* to the eclectic Daoist text the *Huainanzi* to the dynastic history of the Han, the *Hanshu (History of the Former Han Dynasty)* (see Huainanzi; Chinese Classics).

As the *li* became more rigid, so did the social classifications. Confucians were privileged in the social hierarchy; they wielded considerable power in their role as the mediators of conflict and as keepers and interpreters of the *li*. The establishment of the Imperial University in the Han, with an examination system based on the Confucian classics as the core curriculum, further solidified the role and position of the Confucian literati in the social hierarchy.

4 The Legalist response

Not surprisingly, there were those who objected to the power granted the literati (and the ruler) in a Confucian *li*-based order. To the Legalists, the Confucian system of *lizhi* was nothing more than 'rule of man' (*renzhi*). The Confucian sage determined what was best in a given situation based on his own judgment and interpretation of the *li* rather than by appeal to fixed standards or laws of general applicability. Accordingly, *lizhi* strengthened the hand of the elitist class by ceding to the literati the discretionary authority to interpret and apply the *li* as they saw fit. In response, the Legalists advocated clearly codified, publicly promulgated laws applicable to commoner and noble alike as a means of undermining the dual class system in which 'the *li* do not reach down to the common people; penal law does not reach up to the great official'.

While advocating the impartial application of publicly codified laws, Legalism was hardly a 'rule of law', which, as applied to contemporary legal systems, at minimum refers to the existence of an institutionally independent and

professionalized judiciary that interprets and applies laws construed as general commands, publicly known, clearly stated, legitimately enacted and altered, and backed up by the coercive power of the state (see Law, philosophy of). Accordingly, the Legalist *fazhi* is better characterized as rule by law. Law was simply a pragmatic tool for obtaining and maintaining political control and social order. In the Legalist view, humans are self-interested. To avoid conflict and achieve order, they must be manipulated through a reliable and impartial system of rewards and punishments. Clear, codified, public law lets every person know what is expected and what the consequences of their actions will be.

Law was also a pragmatic tool in the sense that the Legalists understood that reliance on the personal qualities and judgment of the ruler would in many instances, if not most, lead to disarray. According to Han Feizi, most rulers are simply average in their abilities: the truly exemplary ruler such as Yao or Shun is as rare as the truly evil and incompetent ruler such as Jie or Zhou. Thus the Legalists sought to design a system that would work even with - or despite - a ruler who is neither exceptionally bright, morally good or politically adept. To do this, they had to conceal the weaknesses of the ruler by erecting a screen of institutional mechanisms, political strategies and techniques (*shu*). Law was one such mechanism. Once the system of laws with their attendant punishments was made known, the laws were to be impartially applied. Neither the ruler nor the bureaucrat who applied the law on a daily basis was to allow personal bias or relationships to sway the outcome. In fact, Han Feizi encouraged the ruler to remain behind the scenes and allow his ministers to carry out the day to day functions of governance. This was the Legalist understanding of *wuwei* - literally, non-action - that is so central to Laozi's Daoist philosophy (see Daoist philosophy §6).

Nevertheless, the ruler remained the ultimate authority, both in theory and practice. In the final analysis, law was what pleased the ruler. Accordingly, the ruler retained the authority to promulgate and change laws. Further, although the Legalists advised the ruler against lightly changing the laws, they did allow that laws should be changed when their costs outweighed their benefits. In a direct attack on the importance invested by the Confucians in the *li*, the Legalists cautioned against undue reverence toward outdated norms.

In sum, Legalist law was positive law, not natural law. It was a pragmatic tool for effecting social order. While law was intended as a means to limit the arbitrary power of the ruling class and the ruler, Legalist *fazhi* or rule by law ultimately failed, as did Confucius' *lizhi* or rites-based order, to impose effective checks on the ruler. By allowing the ruler the final word, Legalism lent theoretical legitimacy to the excesses of the first Emperor of the Qin, the first emperor to unite China whose reign, marked by strict laws and draconian punishments, was short-lived.

5 Huang-Lao: a natural law alternative

There arose in response to the deficiencies of both Confucianism and Legalism a new school, the Huang-Lao school, which flourished during the early Han period (*circa* 200 BC). Huang-Lao attempted to limit the power of the ruler and provide a theoretical and moral foundation for a law-based rule (*fazhi*) by grounding the sociopolitical order in a normatively predetermined natural order. Ultimate authority lies not with the ruler but with the Way (*dao*). The Way/*dao* gives rise to or determines the laws (*dao sheng fa*); the ruler is merely the medium who by overcoming personal, subjective biases is able to apprehend the objectively given Way. Laws are therefore determinate normative standards to be discovered by the sage-ruler: 'There is a distinction between right and wrong: use the law to adjudicate between them. Being empty, tranquil and listening attentively, take the law as the tally.'

Just as the sage is responsible for discovering the law but not for creating it, so is he responsible for impartially applying the law but not for interpreting it. In the legal empire of Huang-Lao, the scales of justice are finely calibrated objective standards. Discretion is eliminated. It is neither the sage's duty nor his role to balance the arguments pro and con in light of the particular circumstances or the culturally and historically contingent norms, attitudes and beliefs of a particular community (in other words, the *li*). Unlike his Confucian (and Daoist) counterpart, the Huang-Lao sage is not called upon to build a consensus out of dissension, to realize a harmony amenable to all concerned parties. He is a judge, not a mediator. His task is to decide who is right and who is wrong, nothing more, nothing less. On one side of the scales of justice goes the deed, on the other the Way. The burden on the sage is to eliminate subjective bias so that he is able to apprehend the deed as it actually is and the Way as it should be.

Thus, like the Legalists and contra Confucius, Huang-Lao advocates an impartial application of publicly promulgated, codified laws of general applicability. However, unlike the Legalists, Huang-Lao attempts to constrain the power of the ruler. Whereas the Legalist ruler was the ultimate authority as to what the law is and how it should be interpreted and thus 'above the law', in the Huang-Lao universe the Way is the ultimate authority and thus the ruler, like all others, must abide by the laws. Accordingly, law for Huang-Lao is not merely a political tool to be used by the ruler to further his own ends. The ruler cannot change the law at will, nor can he circumvent it by issuing pardons.

In sum, whereas law for the Legalists was positive law, a pragmatic means of attaining social order, law for Huang-Lao is natural law, grounded in the normatively predetermined natural order or Way. By grounding law in the Way, Huang-Lao attempted to circumscribe the power of the ruler and thereby avoid the evils of the despotic first emperor of China. However, while there may have been limits on the ruler in theory, there were no such limits in practice. Given that there is no way to verify the ruler's claim to have discovered the Way and hence the correct laws, the ruler's power remains as unchecked in practice as that of either the Confucian or Legalist ruler.

6 The evolution of *li* and *fa*: Xunzi's synthesis

In the absence of a clear victor, the *lizhi-fazhi* debate evolved over time, surfacing in slightly altered forms, in different combinations. On a theoretical level, there have been attempts to synthesize *li* and *fa*, as in the writings of Xunzi.

Xunzi, like Hobbes, portrays the human condition as a struggle to overcome self-interest. In antiquity, people lived in a state of nature. Dominated by their inherent tendencies toward self-interestedness, they competed one with the other for the scarce goods available, giving rise to strife and social disorder. To rectify the chaos and set the social order aright required some system of laws or normative guidelines. In explaining the origin of this system, Xunzi turned to the mythical Ancient Kings (whereas Hobbes turned to the myth of the social contract):

> What is the origin of the *li*? I reply, man is born with desires. If his desires are not satisfied for him, he cannot but seek means to satisfy them himself. If there are no limits and degrees to his seeking, then he will inevitably fall to wrangling with other men. From wrangling comes disorder and from disorder comes exhaustion. The Ancient Kings hated such disorder, and therefore they established the *li* in order to curb it, to train men's desires and to provide for their satisfaction…. This is the origin of the *li*.
>
> (*Xunzi*)

Faced with divergent interests and conflicting claims among the members of society, Xunzi turns to the *li* as a mechanism for adjudication and social control. But the *li* do not function alone; they form part of a larger complex of *li yi fa du* (rites, normative judgment, law and statutes). To rule effectively requires use of both *li* and *fa*.

Xunzi differed from Confucius not only in the importance he attached to *fa* but in his conception of *li*. Xunzi saw the *li* as a means of differentiating the various classes or society not just socially but economically. That is, the *li* provided a principle for determining an equitable distribution of the scarce resources available to society: the nobility (including Confucian literati) received more than those at the bottom of the hierarchy. In contrast, Confucius emphasized the integrative, social aspect of the *li* rather than the divisive, economic aspect. The *li* made possible harmonious interaction among the various social groups by providing a common network of behavioural norms. Civil interaction was possible because all shared the *li*.

Furthermore, in synthesizing *li* and *fa*, Xunzi tended to remake the *li* in the image of *fa*. Xunzi's *li* are similar to *fa* in that they require less participation and more compliance than in the case of Confucius. *Li* for Xunzi are norms created and imposed by those in power on those without power, albeit with the interests of the disempowered in mind. The lower classes are not required to participate in generating the *li* or investing the *li* with personal meaning so much as they are required to comply. Hence one finds Xunzi placing great emphasis on moral training and habituation. The goal is to drill on the *li* until one can comply without reflection. To be sure, once one has thoroughly internalized the *li*, one may experiment with them and be flexible in their application. But for most mere compliance is all that is expected.

Another difference is that whereas Confucius' *li* were context-specific, Xunzi's *li* are less so. For Xunzi, the *li* arose as a response to the unchanging nature of humans as self-interested beings. In his view, the ancient sages

were able to take the measure of human nature and design the network of *li* accordingly.

Because human nature is relatively stable, so also are the *li*. This is not to say, however, that the *li* are universal, eternal truths. For Xunzi, the particular laws and *li* by which one adjudicates conflicts and achieves social order are human products, human artifacts. The process by which the sage generates the *li* is one of pragmatic experimentation: ‘The sage gathers together his thoughts and ideas, experiments with various forms of conscious activity, and so produces *li* and sets forth laws and regulations.’

Xunzi realized that circumstances change and that the *li* and laws must change as well. Nevertheless, he was concerned that there be some basic guidelines, a single agreed set of standards, laws and norms for guiding behaviour and resolving conflicts. To change the *li* and laws without regard to whether change is desirable would be both inefficient and unfair in that it would make it impossible for people to plan their futures. When essential, the *li* and laws could be changed. But given the constancy of human nature, there is as a rule little call to do so.

Although differing from Confucius in some respects, Xunzi remains true to his Confucian roots in others. Perhaps most importantly, he allows the sage the ultimate discretion to determine and apply *li* and *fa* based on his own best judgment:

> Just as there are disorderly rulers, but no such thing as a disorderly state, so there are exemplary persons who effect proper order but no such thing as laws that can effect it…. The laws cannot establish themselves and cases cannot determine themselves. Where there is the right person, they exist; where the right person is lost, they perish. Law is the beginnings of proper order, but the exemplary person is the source of laws.
>
> (*Xunzi*)

Xunzi’s goal was clear: to synthesize Legalism’s impartial application of generally applicable laws with Confucius’ concern for a particularized justice achieved through the discretionary judgment of a mediator who looks to the nuanced norms, attitudes and beliefs of the particular parties and community. Problems remained, however. The emphasis on informal means of resolving conflict ceded considerable power to the mediator. On the formal side, the ruler remained largely unchecked. There were no effective institutional impediments to limit the ruler’s power. Finally, like his predecessors, Xunzi offered no protection to the individual against the state.

7 The Confucianization of law and Legalization of Confucianism

Xunzi’s attempt to synthesize *li* and *fa* on a theoretical level was mirrored in practice by the so-called Confucianization of law and, conversely, the Legalization of Confucianism. The Confucianization of law has been discussed and documented by Ch’ü T’ung-Tsu (1961). It refers to the way in which the legal system came to adopt and reflect the important values of Confucianism. No doubt the formal legal system did incorporate and reflect many Confucian values. For example, the legal system paid particular attention to familial relations and filial piety. One of the unpardonable ‘ten offences’ was unfilial behaviour. Another was the murder of one’s parents. But while it was unpardonable for a son to murder his father, the father was permitted to kill or mutilate his unfilial son, as long as he first petitioned the court. Similarly, in keeping with the deference owed to parents, a son could be punished for simply accusing his father. As a result, the law officially permitted a son to conceal the crimes of the parent. One also had a legal duty to support one’s parents (as is still the case). In fact, the legal codes allowed for the non-execution of a criminal so that the criminal could look after his parents.

The influence of Confucianism and the *li* was also reflected in the hierarchical nature of the legal system and the concern for particularized justice. Punishments were meted out in accordance with one’s status and the status of the victim. Officials were treated more favourably than commoners. They could not be arrested, investigated or sentenced without permission of the emperor. Some were exempt from torture for certain crimes. All benefitted from sentence reductions, and could redeem certain punishments either by paying a fine or accepting a demotion. Status was also important for the official *qua* victim. Generally speaking, the higher the status of the victim and the lower the status of the offender, the more severe the punishment.

The law also drew a distinction between free persons and slaves. Slaves and members of the inferior class were punished more severely for killing, injuring, marrying or engaging in illicit sex with a free person or member of superior class than the contrary. Gender, age and moral character were also factors expressly incorporated into the legal codes’ scheme of punishment.

The influence of Confucianism on the legal system is equally apparent in the seriousness with which the system treated homicide and personal injury. Such crimes were punished with particular severity because they undermined the Confucian *lizhi* system. The Confucian approach to conflict resolution is one of persuasion, not force. Disputes are handled outside the courts through informal mediation. To be successful, the parties must be amenable to persuasion, willing to engage in discussion and compromise if necessary. If the situation has deteriorated to the point of violence, the parties will most likely be hostile to each other and less willing to listen to reason and compromise. Violence and killing, therefore, constitute a rejection of the Confucian mediation process. Once they occur, the state is forced to intervene and to mete out a severe punishment as a deterrent.

Of course, the continued reliance on extrajudicial means such as mediation to settle disputes is itself a product of the Confucian *lizhi* tradition. Another product of that tradition is the legal system's enduring tendency to pursue substantive justice at the cost of procedural justice. Perhaps the best indicator of the concern for substantive justice is the ready availability of appeal. Litigants could continue to press their case all the way up to the emperor if they so desired.

More generally, the influence of Confucianism and *lizhi* continued to be felt in the people's attitudes toward law. Most people felt it was a disgrace to be involved in a lawsuit. At trial, one would be forced to kneel and often subjected to torture. Litigation was also expensive, as captured by the Chinese proverb 'win your lawsuit but lose your money'. Thus most people attempted to resolve conflicts through extrajudicial channels if at all possible.

Although much has been made of the Confucianization of the law, equally important, though less discussed, is the 'Legalization' of Confucianism. Perhaps this phenomenon has drawn less attention because law has always played some role in a Confucian world. As noted above, Confucius saw a role for penal law. By the time of Xunzi, the role of law had expanded considerably. The importance of law is even more evident when one turns away from theory and the ideal society envisaged by Confucius and Mencius toward the real world. Recent archeological discoveries reveal, for instance, that contract law existed as early as the Han. In addition, each dynasty had its own legal code, which was often quite developed and intricate, and provided not just a finely calibrated system of punishments, but procedures for appeal and review of cases. The importance of law in pre-modern China is better appreciated if one considers not just the formal legal system, which was predominantly penal, but the full range of legal norms, including clan regulations and the rules of a particular guild or profession, which served at least to some extent as a form of civil law.

It would, therefore, be a mistake to portray pre-modern China according to some idealized Confucian stereotype that discounts the importance of law and minimizes the role of the formal legal system. At the same time, it would be a mistake to present the pre-modern Chinese state as a rule of law in a contemporary Western sense, at least if that is understood to entail equality before the law and the impartial administration of justice by an independent and professional judiciary. The pre-modern legal system continued to reflect the tension between *li* and *fa*, between the goal of a particularized justice that fully accounts for each person's circumstances and role in society and the goal of impartial justice meted out in accordance with rules of general applicability. It was, however, no more successful in its attempt to combine the best of *li* and *fa* in practice than Xunzi was in his attempt to synthesize the two in theory. The problems that threatened to undermine Xunzi's theoretical synthesis surfaced in practice. Corruption was rampant; the wealthy and powerful used their wealth and connections to circumvent justice. The ruler remained unchecked. Individuals were left at the mercy of the powerful state. As a result, the legal system was often feared more than respected, and reformers continued to press for change.

8 *Li* and *fa* in the modern era

The *li*-*fa* debate has continued in the modern era. With modernization as their slogan, turn-of-the-century reformers such as Liang Qichao declared ideological war on Confucianism, arguing for *fazhi* over and against *lizhi* and *renzhi* (rule by man). In the early years after the communist victory, the new regime was forced to turn to legal specialists, most of whom were Nationalist supporters, to design and implement a legal system. At the same time, however, many important positions within the legal system were filled by 'new cadres' appointed not for their legal skills but for ideological dependability. The specialists favoured a rule of law; the new cadres, supported by the central authorities, a more *li*-based 'rule of man'.

Ironically, the politics of the Cultural Revolution provided an interesting twist to the debate, with the post-Mao

government siding with 'revolutionary' Legalism and rule of law and opposing 'revisionist' Confucianism and rule of man. After the lawlessness of the Cultural Revolution and Mao's death, Deng Xiaoping then made reform of the legal system a top priority. For the time being, advocates of rule of law and a formalized legal system continue to have the upper hand.

The ongoing theoretical battle between the supporters of *li* and *fa* has meant in practice wide oscillation between formal and informal means of conflict resolution. During the Mao era, China lacked a formal criminal procedure law. Although the courts remained responsible for punishing major criminals, less informal channels for dispensing justice were equally if not more important. Work and residential units handled minor offences, and the police imposed administrative sanctions ranging from warnings to fines to re-education through labour. Mediation remained popular.

It is important to realize, however, that during the socialist period the state has controlled and continues to control both the formal and informal means of resolving conflict. Mediation committees, even at the neigbourhood level, are part of the state. The goal is to impart socialist ideology, raise the level of political consciousness of the disputants and resolve disputes in a way consistent with the policies of the Communist Party. Thus in many instances, mediation is far from the voluntary process envisaged by many Western advocates of alternative dispute resolution. Participation is often mandatory; there is often little choice but to accept the solution proposed by the mediator.

Furthermore, contemporary mediation and other informal or extrajudicial means of resolving conflict remain subject to abuse. Before, the Confucian literati were responsible for mediating an informal, particularized justice; now it is the *ganbu* (political cadres) that wield authority. When these cadres put their own interests first, the process breaks down and corruption becomes rampant as the parties seek to exercise their connections (*guanxi*) to influence the 'neutral' arbitrator or judge. Accordingly, many reformers have suggested that less emphasis be placed on informal techniques such as mediation and, conversely, the role of the formal legal system expanded. Their belief is that a formal legal process affords one greater procedural rights and protections, whereas more informal approaches too often subject one to abuse by those in power.

On the formal side, however, law and the judiciary remain firmly under the control of the state. The official view continues to be that law is to serve the Party. Ren Jianxin, President of the Supreme Court, recently stated: 'The independent exercise of judicial power by the people's courts occurs under the leadership of the Party. In order to adhere to [that principle] the independent exercise of judicial power by the people's courts must be supervised and supported…. Courts at all levels must consciously keep aligned with the central Party line, obey orders, listen to commands.'

Ironically, recourse to law has often meant harsh punishments in accordance with the latest Party dictates. Normally, the first official reaction to deviant or criminal behaviour is to attempt to informally persuade the violator to reform. Only if the deviant behaviour persists is the violator subject to the formal legal system and increasingly harsh punishments. However, during periods of political instability when the Party feels the need to address a particular pressing issue such as corruption or the outbreak of political demonstrations, the Party will insist that any violators be subject to the full force of the law. Accordingly, law, as for the Legalists, has remained a pragmatic tool to be exploited by those in power.

Despite the turn toward formal law, the influence of the past and *lizhi* thinking remains strong. One indicator is the ongoing concern for mediation and informal, extrajudicial means of conflict resolution. Perhaps most fundamentally, however, *li*-consciousness continues to shape the very understanding of the nature of law. Law, for most, is not understood as a universal norm. Rather, laws are culturally contingent, albeit generally applicable, norms. This understanding of law explains in part the difficulties in US-China discussions of 'human rights'. The US side considers such rights, if not self-evident, at least universally applicable regardless of time and place, historical traditions or level of economic development. In contrast, the Chinese view human rights, and particularly the civil and political human rights championed by the US, as the contingent product of Western Europe's Enlightenment traditions and the current economic and political circumstances of the US itself (see Rights). Although such rights may be worthy goals, they are predicated on assumptions about the nature of the individual, the relationship of the individual to the state, and the normative value of the individual and individual freedom *vis-à-vis* the good of the community and society as a whole. Accordingly, when China complains that the US is

interfering in China's domestic affairs, it is reflecting an understanding of laws, including human rights, as culturally contingent. When China conditions discussion of rights on the other's willingness to 'seek common ground while reserving differences, maintain mutual self-respect and promote understanding and cooperation', as is China's official policy, it is merely reflecting a traditional understanding of the nature of ethical norms and laws and the proper way to resolve conflict, whether interpersonal or international.

Conversely, China's human rights problems are emblematic of long-existing internal tensions in both China's political theory and practice. The human rights problem results in part from a lack of institutional restraints on those in power, which today means the Communist Party. The lack of effective institutional constraints - a professionalized and truly independent judiciary, for example - has been a characteristic of *lizhi* and *fazhi* throughout the ages.

The human rights problem also results from the lack of a constitutional tradition that looks to the constitution as a source of legally enforceable rights. China has had many constitutions: twelve since 1908. Many of these constitutions have set forth an impressive array of individual rights. However, Chinese citizens do not enjoy such rights in practice because the constitution is not justiciable. Rather, the constitution is hortatory: it sets forth the aspirations and goals of society. In that sense, the constitution reflects the Confucian tradition of emphasizing the development of the moral character of people and the role of the government as a provider of moral guidance and a vision of the good life.

Further, the fact that constitutions come and go is consistent with the traditional *lizhi* concern for context-specificity. Chinese constitutions do not set forth universal principles, eternal truths. Rather, they provide a snapshot of the cultural, political, economic and social values important at that particular time to that particular society. For instance, China has recently amended its constitutions to reflect significant changes in the economic system: socialist commodity economy is out, socialist market economy is in. If the political situation changes, and the conservatives and hardliners regain power, the constitution would probably be amended once again: socialist market economy would be out, socialist commodity economy back in.

9 Conclusion

Socialist China has continued to debate the merits of an informal *li*-based type of political order and a more formal *fa*-based political order. Increasingly, the institutional components of a formal legal system are being developed and implemented: a professional judiciary is being trained, new laws are being codified, programs aimed at educating people about the legal system and their rights are beginning to have effect, as evidenced by the dramatic rise in the number of lawsuits.

Nevertheless, critics abound, and many of these continue to raise the banner of *fazhi*. Increasingly, however, *fazhi* is understood as 'rule of law' in the sense of an professionalized and independent judiciary with the institutional integrity and authority to constrain the Party and safeguard individual rights. Whether such a system can be achieved, and how the traditional concern with *li* and informal justice will affect such a system, remains to be seen.

Law, economic approach to

The development of an economic approach to legal practice has been the most important jurisprudential development in the last third of the twentieth century. Economic analysis has been offered as both a positive and a normative jurisprudence: as an analysis of important features of existing legal practices and as an ideal against which these practices ought to be evaluated. For some, economic analysis has a narrow explanatory range (in various fields of private law, corporations and taxation, and anti-trust law, for example), while others make broader claims for its ability to illuminate any area of law. Finally, there is a difference between those who focus on one explanation and those who focus on prediction, but all offer positive economic analysis of law based on the concept of economic efficiency as defined in welfare economics and applied to law by Coase, Posner, Calabresi and others.

1 The concept of economic efficiency

Economics, and social sciences generally, in the early part of this century was under the influence of both utilitarianism and logical positivism. The correct course of conduct would be that which maximized utility (utilitarianism) (see Utilitarianism); the correct social science methodology required that claims be empirically verifiable or testable (logical positivism) (see Positivism in the social sciences §2). This was not an altogether happy marriage, largely because judgments about which course of action are utility-maximizing required judgments of interpersonal utility which were viewed as unverifiable. Because there exists no common metric against which the gains to one person can be compared with the losses others might suffer, social policy assessment of utilitarian terms in particular is thus called into question.

The sociologist Vilfredo Pareto introduced a mechanism for ordering social states that did not require interpersonal comparisons of utility but did allow policy-makers to favour some policies over others as utility-maximizing. This ordering relationship is known as ‘Pareto superiority’: one state of the world, W, is preferable to another, S, provided no one prefers S to W and at least one person prefers W to S (see Pareto principle). Put slightly differently: W is Pareto superior to S if and only if no one is better off in S than in W and at least one person is better off in W than in S. (These two characterizations are sometimes mistakenly equated on the grounds that the only reason why a person would have a preference for one state to another is that they would be better off in one or the other.)

The concept of Pareto optimality is then defined in terms of Pareto superiority. A state, W, is Pareto optimal if there exists no state, S_i, that is Pareto superior to it. The world is Pareto optimal when there are no ways of rearranging holdings (or anything else redistributable) to make at least one person better off without making someone else worse off.

There are obvious limitations to the Pareto rankings. Very few interesting real-world policy choices produce only winners (or, more weakly, produce no losers). Second, Pareto optimality can be extremely indiscriminate. Assuming a starting point in which A has ten units of some resource and B has none, any reallocation can improve B’s standing by harming A’s. Pareto superiority is almost never satisfied in practice, while Pareto optimality is too easily satisfied.

To help alleviate the first problem, several economists have introduced related ranking relationships, the most famous of which is the Kaldor-Hicks criterion: a state of the world, W, is Kaldor-Hicks superior to another state, S, provided that those who gain in going from S to W could compensate those who lose in such a way that, were compensation to occur, W would be Pareto superior to S. In principle, Kaldor-Hicks allows us to compare states that create winners and losers without making interpersonal comparisons, thus extending the Pareto rankings.

Kaldor-Hicks employs a notion of ‘hypothetical compensation’. In contrast, Pareto superiority requires actual compensation (so that losers, when compensated, are no longer losers). Actual compensation may be costly, and in some cases these costs might suffice to eliminate the gains associated with reallocation. From a utilitarian point of view compensation may be self-defeating. But, if the point of the ranking relationship is simply to have a reliable indicator that a policy is utility-increasing, then hypothetical compensation may be all that is required.

Kaldor-Hicks is not, however, a transitive ordering relationship. Two social states may be Kaldor-Hicks superior

to one another. In that case, it is impossible to infer that either has more total utility than the other. Thus Kaldor-Hicks cannot be used to judge the utilitarian merits of various policy options. Numerous variants on the Kaldor-Hicks criterion have been introduced to overcome the intransitivity problem. Tibor Scitovsky, who first established the intransitivity paradox that beset Kaldor-Hicks, developed his own variant, which was shown also to be intransitive by Kenneth Arrow. Of course, one way of obviating the problem would be to make interpersonal comparisons of relative utility, but doubts as to the meaningfulness of such comparisons were precisely what led to the alternative ranking systems.

2 The 'Coase Theorem'

Ronald Coase's seminal piece 'The Problem of Social Cost' (see Coleman and Lange 1992) established the so-called 'Coase Theorem'. In a well-functioning market, individuals trade with one another in ways that benefit all concerned. These exchanges are Pareto superior or Pareto improving (barring adverse third-party effects). In a perfect or idealized market, such exchanges occur until no further mutually advantageous exchanges can be made. At that point the outcome would be Pareto optimal. There are many barriers to successful exchange, however. If property rights are uncertain, then exchange will be difficult. Take the familiar case of the rancher and the farmer. The rancher believes he can raise cattle and the farmer believes he has the right to grow corn. The relevant uncertainty concerns whether, if the rancher's cows eat the farmer's corn, the rancher will be liable in damages to the farmer.

In his essay Coase argues that, under certain conditions, it will not matter from the point of view of efficiency whether the rancher is free to raise as many cows as he would like without being liable to the farmer or whether, instead, the farmer can prohibit the rancher from raising cows altogether. The argument has two parts. First, what would be the efficient allocation of cows and corn?

Suppose the rancher and the farmer were one person, rancher-farmer, then the answer is simple. Each cow imposes costs in terms of corn that will be destroyed by roaming cows. The rational rancher-farmer will continue raising cows until the marginal costs of doing so exceed the marginal benefit. When the rancher-farmer can earn more from the corn their cows would destroy than they would from the cows, then they will stop raising cows. That is the efficient allocation of cows and corn. Any additional cows will be more costly than beneficial.

The second part of the argument is that when rancher and farmer are two individuals they will raise the same allocation of cows and corn they would have as rancher-farmer. This is so no matter which party has relevant right. Suppose that the rancher and the farmer are fully rational, informed about each other's preferences and, finally, that the transaction costs between them are trivial. Then suppose that the farmer is entitled to prohibit the rancher from raising cows altogether. We know from the above discussion that the value of the last bit of corn to the farmer is less valuable than is the first cow to the rancher. Thus, the rancher can afford to offer the farmer a sum of money equal to, or somewhat greater than, the value of the lost corn to the farmer (and less than the value of the first cow to the rancher). Accepting that sum will make the farmer better off and the rancher will have his first cow. This will apply right until that point at which the rancher will be unwilling to pay the farmer an amount of money equal to the value of the corn the farmer will lose. This is just another way of saying that the value of the next cow will fall below the value of the forgone corn. When that occurs, no further transactions will occur. The net effect will be an efficient allocation of cows and corn.

Conversely, it is easy to see that this same line of argument would work were we to begin with the assumption that the rancher had a right to raise as many cows as he would like free from liability to the farmer. The last cow is less valuable to him than is the first bushel of corn to the farmer. The farmer would be in a position to offer the rancher a mutually advantageous exchange: cows for corn. This will go on until it is no longer rational for the farmer to purchase rights from the rancher. And that will be the efficient point at which no more mutually advantageous trades can be made.

One way of looking at the Coase Theorem is that when there are barriers to market exchange that would otherwise be mutually advantageous or efficient, then the best first option is to see if a secondary market can be set up that allows individuals to contract around their problem. In this case, the barrier to efficiency is an *externality*, that is, the social costs cows impose on corn; the solution is transactions (themselves made possible by the absence of transaction costs). Always look to the contract or the market solution. Why? Simply because such a process

assures Pareto improvements: rational, fully informed agents make mutually advantageous exchanges.

But when the market fails and it is too costly to create secondary markets, then look to the law to establish legal rights and duties that mimic the outcome the market process would have come to had the transaction costs been less troublesome. When it is not possible completely to mimic the efficient outcome, the law should do what it can to reduce transaction costs and encourage private solutions.

3 The Coase Theorem in action: contracts and torts

In a fully specified contract, all the parties would anticipate and respond to all possible contingencies. Nothing could happen in the future that the parties had not contemplated and responded to. For a variety of reasons, no contract is fully specified. Some contingencies are not accounted for in a normal contract. That does not mean, unfortunately, that none of those unlikely events will come about. How should the costs of such an event be allocated among parties who have not determined in advance how they would allocate the risks between or among themselves?

There is always a possibility that the parties could work it out privately. Suppose they cannot, and the matter comes to a court. What should the court do? What rule should the court apply in *default* of the parties having an explicit arrangement? One answer, suggested by the Coase Theorem, is that the court should impose the allocation of rights and responsibilities the parties would have come to themselves had transaction costs not made it impossible for them to contract such an arrangement. There is another alternative that also has links to the original Coase article. The court should forget about the two parties currently before it. Instead it should focus on future contracting parties. In doing so it should set default provisions that will encourage future contractors to reveal information that it would be socially desirable for them to reveal but which neither party would normally have a rational self-interest in revealing. So we can use the default rule to promote efficiency in at least two different ways: either by minimizing transaction costs so that the parties can spend the resources they have in areas that are more important to them, or by promoting *socially* efficient revelation of information by future contracting parties.

Now to torts. A injures B. Should A be made to pay B's costs or should they be required to shoulder their own costs? Should a rule of fault or of strict liability be applied? If A has to bear B's costs whether or not A is at fault (strict liability), that would be just like making A be the 'owner' of both activities, by making A the owner of B's costs. Even if A has to bear B's costs, it does not mean that A will no longer injure B. Rather, A will decide whether it is worth it to injure B and bear the costs or whether it is better to forego the injurious activity. That, in turn, depends on the relative costs and benefits. In economics, this practice of forcing A to bear the costs he imposes on B is referred to as *internalizing externalities*. A rule of strict liability appears to lead to efficient outcomes in just the way the rancher-farmer example does.

The goal of tort law is not to eliminate accidents altogether. After all, the costs of preventing an accident may exceed the costs of the accident itself. It may cost $100 to prevent a $50 accident, and that would not be rational. If it would have cost A that much to prevent a similar injury to B, he would not have prevented the injury. Instead he would have risked the injury and saved $50.

The goal is not to avoid accidents but to minimize the sum of the costs of accidents and the costs of avoiding them. Sometimes minimizing costs means reducing the probability of an accident's occurrence. Sometimes reducing the probability requires that precautions be undertaken by both injurers and victims. A rule of strict liability will not give a victim any incentive to take precautions, because the victim is fully compensated for his loss. Why would he accept any additional costs? A rule of strict liability will not be efficient under such circumstances.

Consider the alternative. Under a rule of negligence, an injurer will not be liable unless he is at fault or negligent in causing another harm. What do we mean by negligence? In economic analysis, negligence is the failure to take cost-justified precautions. Precautions are cost-justified when incurring them is less costly than the injury they are designed to prevent, discounted by the probability of its occurrence. So failure to take precautions would be negligent if it would cost $50 to prevent a $100 accident - but not if it would cost $150 to prevent the same accident.

It will always be rational for an injurer to take all cost-justified precautions under a negligence rule. If he does, he escapes liability; if he does not, he will bear the full costs of the accident which, *ex hypothesi*, exceed his

prevention costs. Thus, rational agents will not be negligent. Because the injurer always takes rational precautions, the accidents that occur are not his fault. That means the victim will have to bear his own costs under a negligence rule, and hence will always have a similar incentive to take all cost-justified precautions. If he can reduce the probability of his incurring costs by taking precautions that are less costly than the harm, then he will do so; and so on. Thus, there will be cases when it would make sense to have a rule of negligence, and other times when a rule of strict liability will be in order.

Law, Islamic philosophy of

*One of the principles of Islam which precedes juristic discussion proper is that God, the creator and lord of the world, has commissioned humanity to believe, confess and act in particular ways. The details of this commission (*taklif*) were handed down through a sequence of prophets, culminating in Muhammad, and were then embedded in two literary structures which together constitute revelation (*wahy*): the Qur'an, which is the word of God, and the* hadith*, short narratives of the prophet's life and sayings which give expression to his (and his community's) ideal practice or* sunna*. The totality of beliefs and rules that can be derived from these sources constitutes God's law or* shari'a.

Juristic literature has generated two major literary genres. One, known as usul al-fiqh *(roots of jurisprudence), deals with hermeneutical principles that can be used for deriving rules from revelation; it represents, in part, something like a philosophy of law. The other, dominant genre,* furu' al-fiqh *(branches of jurisprudence), is an elaboration of rules which govern ritual and social activities. An overall philosophy of law in Islam, not fully articulated in the pre-modern tradition, can only be discovered through consideration of both genres.*

1 Revelation

In Islamic belief there are a number of principles, derived from the exercise of the intellect or from history, which precede juristic discussion proper. These include, for example, that God exists, that he is creator and lord of the world, and that he has commissioned humanity to believe, confess and act in particular ways. The details of God's commission (*taklif*) have been mediated through a sequence of prophets culminating in the seal of all the prophets, Muhammad, whose message abrogates previous messages and is for all peoples. With the death of the Prophet, the divine command has been embedded in two literary structures which together constitute revelation (*wahy*): the Qur'an, which is the word of God, a miracle, and the *hadith*, short narratives of the Prophet's life and sayings which give expression to his (and his community's) ideal practice or *sunna*. The totality of beliefs and rules that can be derived from these sources constitute God's law or *shari'a* (see Islamic theology).

The Qur'an is usually deemed to contain no more than about 500 verses of legal import. The body of *hadith* was immensely larger. It was contained in a number of admired collections, the core of which included, for the mainstream Sunni community, the pre-eminent collections of Bukhari (d. AH 256/AD 870) and Muslim ibn al-Hajjaj (d. AH 261/AD 875). Beyond these, there were a number of collections that might be brought into the play of juristic discussion; the major sectarian group, the Shi'is, also had their own collections. The vast bulk of *hadith* material, as contrasted with the modest quantity of juristic material in the Qur'an, ensured that *hadith* was in practice the dominant element of revelation in hermeneutical discussions. The Book is more in need of the *sunna* than the *sunna* of the Book, said the Syrian jurist Awza'i (d. AH 157/AD 774), echoing the efforts of other scholars to articulate the controlling effects (judging, abrogating and explaining) of *sunna* on the Qur'an.

2 *Usul al-fiqh*

The literary tradition of *usul al-fiqh* (roots of jurisprudence) is usually thought to begin with the *Risala* of Muhammad ibn Idris al-Shafi'i in the third century AH (ninth century AD). However, there is then a hiatus between this work and the emergence, some two centuries later, of other works of the same kind. Modern scholars have put this down to pseudepigraphy, or to the community's engagement with theological and intellectual problems. Once established, this tradition, although it developed in a variety of ways, showed remarkable structural and conceptual unity over the centuries, with individual books always including a presentation of hermeneutical principles and an elaboration of the theory of *ijtihad* (independent judgment).

Since revelation was constituted by written texts, a primary bundle of hermeneutical techniques related to linguistic and rhetorical structures. These were usually presented under simple antithetical headings (the general and the particular, commands and prohibitions, the clear and the ambiguous, the absolute and the qualified, truth and metaphor and so on), which might or might not be integrated into a general theory of language and rhetoric. Consideration was given to the principle of abrogation (*naskh*), a result of diachronic revelation, and (with reference to *hadith* only) to the mode of transmission, which was either general report (*tawatur*, giving rise to certain knowledge) or isolated report (*ahad*, giving rise to uncertain knowledge or opinion). Consensus (*ijma'*),

whether of the community or of scholars, on the meanings of revelation was discussed, as was the operation of analogy (*qiyas*) as a means (variously qualified) to permit extrapolation of rules from a finite body of revealed texts. These, together with a limited number of extra items, either of substance (such as the opinions of the Prophet’s companions) or of judgment (such as the relevance of *maslaha*, or social welfare) represented the major focuses of analysis and discussion within a single and more or less unified literary tradition for about a thousand years. The hermeneutical loyalties of the mainstream Sunni community were summarized by reference to the four principles (*usul*) of Qur’an, *sunna*, consensus and analogy.

The whole bundle of interpretative devices and principles of judgment was acknowledged to lead to conflicting possibilities (*ta‘arud*) and to the necessity for rational and justified preference (*tarjih*). The context and the significance of juristic preference depended on the theory of *ijtihad*, the expression of which was a culmination and a kind of resolution for all other arguments in a work of *usul*. *Ijtihad* literally means effort; technically, it means the exertion of the utmost possible effort by a trained jurist, taking into account all the relevant texts of revelation and principles of interpretation, in order to discover, for a particular human situation, a rule of law. Underlying this definition there is an important epistemological principle. It concedes that most of the details of the law are not known (not certain) but are a matter of skilled (and preferably pious) deduction on the basis of principles that are themselves subject to debate and incapable of providing certainty.

Within this area, the jurists were committed to acknowledging the views of other jurists, if adequately defended, and to the elaboration of systematic arguments to defend their own views. Committed in this respect to debate and uncertainty, the jurists (in this context *mujtahids*, those who undertake *ijtihad*) also acknowledged a need for final decisions in particular cases. This was provided by asserting that the result of an act of *ijtihad* was binding both on the *mujtahid* himself and, where relevant, on those who were not experts in the law and could not participate in juristic debate (*muqallids*). These, by an exercise of choice (which was itself an act of *ijtihad*), were required to commit themselves to a particular *mujtahid* and to accept his rulings. The theory of *ijtihad* thus provides both an epistemology (permitting and encouraging debate and intellectual play) and a structure of authority. In its former aspect it accounts (in part) for the vitality of the tradition of *furu‘ al-fiqh*, and in its latter aspect it justifies the participation of the jurists in positions of authority, notably as judges (*qadis*) and the jurisconsults (*muftis*).

The structures set out above, which were capable of considerable and diverse development, represent the main features of *usul* literature for both the Sunni community and for the Shi‘is. The latter differed from the Sunnis in rejecting most forms of analogical argument. Summarizing their *usul*, they substituted for the Sunni principle of analogy that of intellect (*‘aql*) deemed by them (but not by the Sunnis) to be capable of independent moral judgment. The Shi‘i community was initially suspicious of the theory of *ijtihad* (perhaps because it too easily acknowledged plurality and uncertainty in the law), but it was integrated into their works of *usul* from the time of ‘Allamah al-Hili in the eighth century AH (fourteenth century AD). Amongst the standard classics of the Sunni tradition are the *Mustasfa* of al-Ghazali (§2) and the *Muwafaqat* of Shatibi (d. AH 790/AD 1388), showing an original foregrounding of the principle of *maslaha*. One of the outstanding *usul* writers of the Shi‘i tradition after ‘Allamah is the nineteenth-century Shaykh Murtada ibn Muhammad Ansari.

3 *Furu‘ al-fiqh*

The other major genre of juristic literature, *furu‘ al-fiqh* (branches of jurisprudence), is constituted primarily by rules (positive law). It might be expected that individual writers in this genre were, from generation to generation, engaged in the process of *ijtihad*. However, this is not quite the case. In the course of the ninth and tenth centuries AD, the Islamic community became committed to a pattern of juristic loyalties whereby, in the end, all Muslims identified themselves with particular schools (*madhahib*) of the law. Within the Sunni tradition there were four dominant schools, the Maliki, Hanafi, Shafi‘i and Hanbali schools, each named after its founder. These acknowledged each other and also gave qualified acknowledgement to a number of minor schools, and to the Shi‘is. The vast majority of significant jurists belonged to one of the major schools, usually by virtue of birth and geography, only rarely by choice and adoption. When they wrote a work of *furu‘ al-fiqh*, they gave expression to the rules (with the attendant patterns of dispute and debate) that they had inherited within their school. The fundamental acts of *ijtihad* were thus projected back to the founder and to the early masters. By an ongoing act of loyalty, commitment and preservation, successive generations of jurists rediscovered and restated the rules of the tradition to which they belonged.

Works of *furu‘* therefore show a dominant hermeneutical orientation towards earlier works in their own tradition, and not towards revelation. This is reflected in the characteristic patterns of citation, which invariably recall the opinions and judgments of earlier masters within the school, and the literary forms of such works (epitome, commentary, supercommentary), all marks of hermeneutical commitment to a particular school. In so far as writers in this tradition actually deployed arguments of the type described in works of *usul*, they did so in order to demonstrate that the inherited structure of rules could be aligned with revelation and not for the purposes of *ab initio* deduction of the law. Developments in the law, manipulation of its concepts and their application to new cases were always carried out in the light of the inherited structure. The inconcinnity between the principles of jurisprudence as set out in a work of *usul* and the practice of a writing jurist was eventually acknowledged with the recognition that, in relation to the school founders, these were principles of discovery while, in relation to later jurists, they were principles of justification. Hermeneutical thinking within the tradition (based on juristic texts, not texts of revelation) was known as *ijtihad fi ’l-madhhab* or school-*ijtihad* and distinguished from the independent *ijtihad* of the founding figures.

4 Contemporary trends

Muslim thinkers of the twentieth century, committed to various programmes of legal reform or political action, have developed a number of theoretical props which take them away from the traditional modes of juristic expression. They have often abandoned the particularity of school loyalties; instead, they have adopted law-drafting techniques that reflect the realities of modern nation-states, borrowed legal and social principles from a variety of sources, and argued strenuously that the door of independent *ijtihad* is open, meaning that they can again make independent legal judgments based on direct confrontation with revelation (often using a definition of revelation, at least in relation to *hadith*, which is more limited than that of the past). The major, and certainly the most obvious, modern responses to the juristic tradition have been practical, either in the service of state law or in the service of political opposition. There has been a corresponding lack of interest in the philosophy that is articulated in the traditional forms of juristic discourse, especially those of *furu‘*. In different ways, both of the traditional genres, *usul* and *furu‘*, acknowledge the exploratory nature of the effort of defining God’s law and situate themselves in a flexible and pluralist system of rules. They may have more relevance to contemporary problems than is generally conceded (see Islamic philosophy, modern).

The modern linguistic calque *falsafat al-tashri‘* (philosophy of legislation) or its equivalent is currently used in several Islamic countries to designate a variety of academic activities. These range from conservative scholarship, drawing heavily on the tradition of *usul al-fiqh*, to analytic descriptions of legal developments in modern Islamic states and something like the Western discipline of philosophy of law.

Law, limits of

Questions concerning the proper limits of law are of particular interest to thinkers in the Western political tradition of individualism. In this tradition the law is regarded primarily as an instrument of coercion and the problem is to define the scope of law in such a way that it fulfils its necessary purposes at minimum cost to individual liberty. Debate therefore centres on the proper ends of legal coercion. Two law-limiting strategies are commonly adopted; the practical and the moral. As the most important ends of human life (salvation of the soul, or its secular equivalent, moral integrity) are taken to require the uncoerced, 'inward', assent of the individual, the effective scope of the law is significantly limited on practical grounds to the regulation of 'outward' behaviour. On the moral question concerning which behaviour ought to fall within the purview of the law, conservatives contend that society has a right to enforce its moral values by criminalizing whatever behaviour its members regard as 'sinful'. The characteristic strategy of liberals is to respond by arguing that unorthodox or unpopular activities must clearly be shown to be 'harmful' before they may properly be outlawed. Much debate focuses upon the interpretation of this principle (the 'harm principle'), particularly what is to count as 'harm' for purposes of legislation, and whose harm is properly in question. Dissatisfaction on these crucial issues has led some liberals to reject what they consider to be the fruitless attempt to draw the line between liberty and law by balancing individual against social harm in favour of various theories of individual rights, while it has led others (communitarians and some feminists) to question the individualist assumptions in terms of which the problem of the limits of law gains its especial urgency.

1 Individualism and the limits of law

Should the law be used to promote religion, regulate trade and 'enforce morals'? Or, should it be narrowly confined to the bare essentials of preserving the peace and preventing violence? The question of the proper limits of law was at best a marginal one for the ancient Greeks and the medievals, and remains so today for many non-Western thinkers. It is, however, an issue which has been of particular concern within the modern (post-sixteenth century) Western tradition of political thought, a preoccupation reflecting the importance accorded to individual liberty in this tradition, together with the marked cultural diversity of modern Western societies and the unprecedented growth in the power of the state. The conceptual background against which the question of the proper limits of law is most naturally raised is one of 'individualism', according to which society is composed of independent individuals who associate politically on the basis of a mutual sacrifice of liberty in return for the various benefits of social cooperation. This view encourages a search for reasons or principles which may be used to assess the appropriateness both of existing laws and of proposed legislation by defining the proper balance between individual liberty and state power. 'Appropriateness' may, however, mean either practical efficiency or moral rightness (see Liberalism §3).

2 Practical limits to law

It is manifestly desirable that laws be efficient; the proposed ends of the law should be achievable by the means available to the law. Now the law, broadly understood as a system of rules established by a legal authority requiring us to do or forbear on pain of punishment, ultimately relies upon coercion for its enforcement (see Law, philosophy of). Consequently, the scope of the law is limited to those ends which can be attained by regulating *behaviour* by playing upon *fear*. Locke deployed the efficiency argument against the state enforcement of religion. Beginning from the proposition that the main purpose of religion is the salvation of souls, which requires an unforced act of faith on the part of the individual believer, he argued that legislators who set out to enforce religion can at best compel 'outward conformity' rather than genuine conviction of belief (see Toleration §1). Hence the legal enforcement of religious orthodoxy commits a practical error - it mismatches means and ends. The efficiency argument thus sets limits to the scope of law by dividing society into separate spheres, in Locke's case the religious and the secular, legal coercion being confined strictly to the latter. Later liberals confine the scope of state action even within the secular sphere itself, especially in respect of morality and economics (see Smith, A.). In regard to morality the argument focuses upon the conditions for the attainment of moral virtue. Thus, Kant argued that a morally good person is someone who not only does the right thing, but does it for morally the right reasons (see Kant, I. §10). As the freely adopted intentions of the agent are of paramount ethical concern, the (positive) promotion of virtue is assigned to education and placed permanently beyond the reach of the rough

coercive engine of the law, which is restricted to the more modest role of the (negative) prevention of vice.

The efficiency argument well reveals the twin poles around which liberal individualism revolves: reverence of individual freedom of choice and a corresponding distaste for legal coercion. The position, however, has its weaknesses. In particular, it takes a debatably narrow view of the strategies open to legislators. Thus, although 'true faith' might not be directly enforceable, it might still be produced by indirect means, for example, by banning religious competition, censorship and by controlling education. Likewise, the Kantian position on moral goodness perhaps underestimates the scope for indirect coercion by way of using the law to sustain a framework of broadly educative institutions and practices within which morally desirable motives might be elicited and encouraged. Even so, these possibilities raise in their turn difficult questions concerning the 'authenticity' of beliefs and the 'genuineness' of motives produced by such methods of 'social engineering'. At this point the efficiency argument leads on to issues connected with freedom of the will and human agency, and to questions concerning the nature of law and the educative role of the state (see Free will; Autonomy, ethical).

3 Moral limits to law

What the law *can* do is one thing; what it *ought* to do is another. A useful way of approaching the moral question is to ask how far law should go in pursuit of the essentially negative and in general perfectly feasible goal of preventing vice. Clearly, no morally defensible legal system can permit murder and rape, ignore violence and intimidation, or countenance gross dishonesty and theft. Peace and security, the basic prerequisites of any minimally tolerable social life, are universally essential moral ends. But ought the law to be narrowly confined to securing this 'moral minimum', or should it be extended to regulate those less immediately vital aspects of our relations with others which nonetheless often express passionately held convictions about right and wrong, serve to distinguish the characteristic ethos of one community from that of another, and even to define our own sense of moral identity and personal worth?

On this question two contending schools of thought may be distinguished: conservatism and liberalism. The case for legal conservatism goes as follows. Murder, rape, theft and the like are evil acts. By outlawing evil the law expresses our deep and abiding moral convictions and, by convicting and punishing the criminal, the judge and jury give emphatic vent to our community's shared sense of moral outrage and disgust. The reach of the law is thus virtually unlimited: it stretches as far as the community's sense of sin. The chief difficulty with the conservative doctrine is that, murder and the like aside, it is far from obvious that the criminal law can any longer act (if it ever did) as the legal vehicle of a commonly shared morality. Indeed, the problem of the limits of law is an acute one precisely because little general agreement is to be found on such questions as euthanasia, abortion, genetic engineering, pornography, homosexuality, the selling and consumption of addictive drugs, 'politically correct' language, or the killing or mistreatment of animals. Thus, although legal conservatism often sails under the colours of moral populism, it sanctions the dogmatic imposition of a morality which might have little support beyond the accidental prejudices of the notoriously introverted judicial mind. Hence the need, in the liberal view, for a clear and rationally defensible moral principle which affords a critical perspective on the ends of law.

4 Law-limiting principles and the crisis of liberalism

The fruits of the liberal quest for a morally justifiable law-limiting principle have taken two main forms. The first is the Principle of Equal Freedom: 'People should be legally free to do as they please providing only that they do not interfere with the like liberty of others'. This principle reflects the liberal's concern that the state should act merely as a neutral referee of people's freely chosen activities rather than determining their ends and directing their lives (see Neutrality, political). But because it fails to specify concretely what people should be free to do, a law permitting bodily assault would satisfy the rule just as well as one prohibiting it. By contrast its rival, the harm principle, has the immediate advantage of connecting substantively with the most intuitively arresting feature of our moral minimum. The advocates of the harm principle readily concede that we are properly morally outraged by murder and the like but, *pace* the conservative, it is the objective harm done, and not the subjective feelings of the community, that justifies the criminalization of these activities. In addition, the harm principle is advanced as furnishing an empirically applicable decision procedure for rationally resolving disagreements upon cases beyond the moral minimum, and especially upon the more controversial ones such as 'victimless crimes' of the kind alluded to above.

The harm principle was classically formulated by the utilitarian philosopher J.S. Mill (§12). Mill argued that the general happiness is maximized only when coercive interference with the individual is rigorously restricted to that unavoidably necessary to 'prevent harm to others'. A great deal of contemporary discussion of the limits of law is concerned with the interpretation of Mill's version of the principle. Two questions are particularly pressing: what is to count as 'harm' for the purposes of legislation? and whose harm is properly at issue?

Physical injury clearly counts as harm for the purposes of legislation, but what about injuries sustained by voluntary participants in competitive sports? We clearly need to qualify the principle with a sub-rule of non-consent to cover cases of this kind; and this in turn raises the question of what is to count as consent - explicit agreement? tacit consent? passive acquiescence? (see Consent). Moreover, does harm extend to psychological harm, and does that in turn stretch to emotional hurt? If so, should offensive behaviour fall under a legal ban too? And is behaviour offensive if any one person is liable to be upset by it? Clearly, if we concede too much in this direction the protected sphere of liberty is in danger of shrinking to a nullity; a line must be drawn, yet drawing it at any particular point smacks of arbitrariness. Mill himself is by no means clear on these questions but it has been argued that we can sort out the legally relevant harms in terms of 'set-backs' to *interests* (see Needs and interests §1). Physical injuries, psychological traumas and the like set us back in the sense of preventing us from effectively pursuing our chosen ends; they thus harm our interests and may properly be forbidden. Lesser hurts do not set our interests back and must therefore be permitted. However, serious set-backs can occur to an individual's economic and professional interests in competitive settings which are not themselves undesirable. What is required therefore is a tenable conception of a wrongful harm or set-back, something that is unlikely to be supplied outside the context of a general and inclusive moral theory. Mill believes that he has such a thing in utilitarianism. The weakness of utilitarianism in the eyes of many liberals, however, lies precisely in its tendency to subordinate the individual to the general interest (see Utilitarianism).

Similar difficulties attend the question of whose harm is at issue. Mill himself takes a radical line here, rejecting all laws against self-inflicted harm on the grounds that they constitute a paternalistic interference with the freedom of adults to live their own lives and make their own mistakes; a position on the face of it scarcely consistent with the maximization of general utility and one which also implies highly controversial conclusions about drug taking, euthanasia, sadomasochistic sex, and so on (see Paternalism). Equally problematical is the question of whether the principle should be restricted to harm to other *individuals* (including foetuses?) or should encompass harm to *society*, including its political institutions and practices, together with basic social forms such as the family and associated values and ideals. This was the issue of a celebrated debate between the eminent English judge Lord Devlin and the influential legal philosopher H.L.A. Hart concerning the legalization of homosexuality. Devlin argues that if the purpose of the criminal law were simply to protect the individual from harm the consent of the victim of an assault or a rape would be a complete defence, but quite properly the law pursues the assailant, irrespective of consent; and it does so because it represents the profound interest society has in the integrity of the rules which protect the welfare of all its members. Given that the purpose of the criminal law is thus primarily to protect society rather than the individual, Devlin infers that homosexuals enjoy no unconditional right to pursue their consensual activities, for the law may always legitimately ask whether, in so doing, they harm or undermine institutions (such as the family) or values (such as heterosexual love) essential to society's survival or wellbeing (see Devlin 1965). And the conclusion may be generalized: no socially unorthodox activity can claim to be, as a matter of principle, 'not the law's business'.

The import of Devlin's quasi-conservative argument is thus seriously to challenge the grounds of the distinction, so vital to the liberal campaign to limit the scope of law, between the private and the public spheres of society (see Privacy). What is particularly significant about Hart's response (1963) to Devlin is that it reveals the vulnerability of utility-based liberal individualism. Thus, *qua* utilitarian, Hart absorbs the force of Devlin's argument concerning the social purpose of the law, extends the harm principle to society, and concentrates his defence of individual liberty upon Devlin's claim as to what in fact constitutes social danger - in his opinion, Devlin's fear that homosexuality threatens the collapse of society is no more credible than the emperor Justinian's conviction that it is the cause of earthquakes. It is not clear, however, that Devlin does, or needs to, go further than the proposition that heterodox activities might constitute a significant danger to society to make his point. In any event, the effect of the Hart-Devlin confrontation is so to shift the debate that the outcome depends on hard-to-verify conjectures about the conditions of social stability and breakdown.

Under pressures of this kind other liberals have tended to fall back upon another Millian idea, that of 'individuality', interpreted as implying that our most vital interest as human beings lies not simply in happiness *per se* but rather in the specific satisfactions associated with developing our autonomy and displaying our individual uniqueness. As individuality essentially involves the outward expression of inward convictions and needs, it entails a presumption in favour of individual liberty in respect of unpopular or unorthodox behaviour sufficiently powerful to counter all but the most overwhelming reasons for legal interference. This raises the objection from socialists, communitarians and some feminists that liberals are prepared to erode the shared practices and values which constitute our identities as social beings in favour of an atomized association of socially disconnected 'abstract' individualists (see Community and communitarianism §3; Feminist political philosophy). Other thinkers, critical of the whole utilitarian idea of aggregating and balancing individual harm against social good, maintain that the scope of law must be limited by a theory of individual rights grounded independently of utility (see Rights; for prominent examples of this position, see Dworkin, R. and Rawls, J.). The question as to the proper limits of law therefore appears increasingly to be embraced within a broader debate as to the philosophical credentials of individualistic liberalism.

Law, philosophy of

Law has been a significant topic for philosophical discussion since its beginnings. Attempts to discover the principles of cosmic order, and to discover or secure the principles of order in human communities, have been the wellsprings of inquiry into law. Such inquiry has probed the nature and being of law, and its virtues, whether those that it is considered as intrinsically possessing, or those that ought to be cultivated by lawgivers, judges or engaged citizens. A dialectic of reason and will is to be found in philosophical speculation about the underpinning principles of law. On the one side, there is the idea that the cosmos itself, and human society too, contain immanent principles of rational or reasonable order, and this order must be capable of discovery or apprehension by rational (or 'reasonable') beings. On the other side, there is the view that order, especially in society and in human conduct, is not found but made, not disclosed to reason but asserted by acts of will. Either there is a 'law of reason - and nature' or there is a 'law by command of the sovereign - or of God'. A third possible element in the discussion may then enter, that of custom as the foundation of law.

Implicit in the opposition of reason and will is the question of practical reason: does reason have a truly practical role concerning ultimate ends and nonderivative principles of action, or is it only ancillary to pursuit of ends or fulfilment of norms set by will? Alternatively, does reason already presuppose custom and usage, and enter the lists only by way of critique of current custom and usage? In either case, what is at issue is the very existence of such a thing as 'practical reason' (see Practical reason and ethics). For law is about human practice, about societal order enforced and upheld. If there can be a law of reason, it must be that reason is a practical as well as a speculative faculty. The radically opposed alternative sets will above reason, will oriented to the ends human beings happen to have. Norms and normative order depend then on what is willed in the way of patterns for conduct; reason plays only an ancillary part in the adjustment of means to ends.

A further fundamental set of questions concerns the linkage of the legal with the political. If law concerns good order, and if politics aims at good order in a polity, law must be a crucial part of politics; but in this case a subordinate part, for politics determines law, but not law politics. On the other hand, politics may be considered at least as much a matter of actual power-structures as a matter of speculation about their beneficial use for some postulated common good. In the latter case, we may see law as that which can in principle set limits on and control abuses of power. Politics is about power, law about the shaping and the limiting of power-structures. The issue then is how to make law a master of politics rather than its servant.

1 Law as reason

In the *Republic*, Plato depicts Thrasymachus, proponent of the thesis that justice is the will of the powerful, as being refuted comprehensively by Socrates (see Plato §14). The refutation postulates a human capability to discern principles of right societal conduct independently of any formal enactment or legislative decision made by somebody with power. These principles in their very nature are normative, not descriptive. In Aristotle, the same general idea emerges in the form of noticing that whereas much that is observed as law is locally variable and arbitrary, there appear to be fundamental common principles across different polities. Some principles may then be legal simply 'by enactment', but others seem to be so 'by nature'. Explorations of the nature of humans as rational and political animals may then help to underpin the idea of that which is right by nature, but that exploration is more the achievement of Aristotle's successors in the Stoic tradition than of himself (see Stoicism §18). Roman jurists adapted some of the Stoic ideas of natural law in their expositions of the civil law, and subsequently, for medieval and early modern Europe, the existence of the Justinianic (see Justinian) compilation of the whole body of Roman law was held by many thinkers to embody in large measure the promise of law as 'written reason' (see Roman law; compare Gaius; Bartolus of Sassoferrato; Pothier, R.J.).

In any event, the greatest flowering of the Aristotelian idea came with its fusion into the Christian tradition in the work of Thomas Aquinas (§13), hugely influential as this has been in the developing of Catholic moral theology in the succeeding centuries. After at least a century of relative neglect among legal scholars, especially in the English-speaking world, the last quarter of the twentieth century has seen a strong revival of the Thomistic approach in the philosophy of law (see Natural law), with contemporary thinkers developing the idea of the basic goods implicit in human nature, and showing both how these can lead to the elaboration of moral principles, and

then how positively enacted laws can be understood as concretizations of fundamental principles.

In the seventeenth century, other strands of essentially the same idea had led to the belief, for example, of Hugo Grotius, that basic principles of right conduct and hence of human rights are themselves ascertainable by intuition and reason (compare Pufendorf, S.; Stair, J.D.). Kant's representation of the principles of practical reason is the classical restatement of this position in its most philosophically rigorous form (see Kant, I. §§9-11; Kantian ethics §1).

In a wide sense, all these approaches may be ascribed to rationalism, as contrasted with voluntarism (see Rationalism; Voluntarism). For they treat law, or its fundamental principles, as discoverable by rational and discursive means, independently of the intervention of any legislative will. They do not, of course, deny the need for legislative, or adjudicative or executive, will. Even if fundamental principles stand to reason, their detailed operationalization in actual societies requires processes of law-stating, law-applying and law-enforcement. But the issue is whether these are fundamentally answerable at the bar of reason and practical wisdom (*prudentia*), or not. To the extent that they are so answerable, we have a concept of some 'higher law', some law of reason, by which to justify, to measure and to criticize the actual practice of human legal institutions. If the rational derivation of this depends in some way on a teleological understanding of human nature and its relation to the creator and the rest of the created universe, we may reasonably enough call this a 'law of nature' or 'natural law'.

2 Law as will

But there is another possible account of higher law. It can be thought of as a law laid down by God for his creation. The divine will, not the divine reason, must be the source of law. It cannot be for created reason to presume to judge of the creator's wisdom. The omnipotence of the creator entails that the law will be whatever the creator wills it to be, and to be law by virtue of that will, not by any independent reason and nature of things. Indeed, the nature of things will be just what the creator wills it to be, and the names of things will be matters of convention derived from human linguistic usage. Concepts are not essences that guide us to essential meanings. Nominalism and voluntarism are inevitable bedfellows (see Nominalism).

It is therefore inaccurate to suppose that the theory of natural law as a kind of higher law presupposes rationalism. There can indeed be a voluntaristic species of 'natural law', though the voluntaristic tradition will more likely speak of 'divine law' or 'God's law' than of natural law *simpliciter* (see Austin, J.). Moreover, one element in the religious upheavals associated with the Reformation was an insistence on the need for unmediated regard to the (scripturally revealed) divine law, rather than to the custom or tradition of sinful human institutions such as the Church. It is not for fallen human reason to set itself above or even beside the revealed will of God. But that revealed will must be received as a law binding above all others.

In this state of things it becomes questionable whether to accept any human law at all; and, on the voluntarist hypothesis, to see how law other than God's law can have any obligatory force at all. To the saving of human law there are only two possible moves: either it must be shown that God in fact wills our obedience to the very kings and other superiors we actually have (as in the theory of 'the divine right of kings'), or it must be the case that the binding will arises from the consent of human beings themselves, expressed through some original social contract. The divine will then enters the picture only to the extent of making obligatory the fulfilment of compacts voluntarily agreed, a point to which may be added a grimly Hobbesian acknowledgement that covenants without swords are but words, so the true binding force of the obligation of the law will derive from the effective might of the very ruler whom the social compact institutes in that office (see Hobbes, T. §§6-7). In this Hobbesian form, natural law has practically reached a vanishing point (though Locke's response envisages the state of nature as governed by reason in the form of a law of nature, grounding presocietal rights of human beings to life, liberty and estate (see Locke, J. §§9-10). The greatest legal expression of the Lockean vision of law, applied to expounding the English common law, is in the work of Sir William Blackstone. The *coup de grâce* was administered by Hume and Bentham, the latter having as his particular target Blackstone's work. They argue that the social contract is a fifth wheel on the carriage in either Hobbesian or Lockean form, since all the reasons that there are for obeying the law that we have supposedly agreed to apply with equal force even if we did not agree to it, and there is no evidence anywhere of any such agreement as a historical phenomenon (see Bentham, J. §6).

3 Law as custom

Whence then comes the law? Hume ascribes it to convention and custom primarily, coupled with reflection upon the pleasing quality (the utility) of rigorous observance of customary norms (see Hume, D. §5). Bentham and Austin restrict the role of custom or 'habit' to the issue of obedience. Whoever is habitually obeyed by the many in a numerous society is in a position to enforce their commands by effectively coercive sanctions up to and including death. Thus do they differentiate the positive law from other forms of so-called law such as scientific law, laws of honour, or personal moral codes. Law is such by command of a sovereign, the one habitually obeyed who habitually obeys no other (see Sovereignty).

Legal positivism of this stamp is an easy bedfellow with political utilitarianism, and programmes of legal reform. Codification of law is an associated ambition, justified on utilitarian grounds (see Utilitarianism). Codification is also a distinctive phenomenon of the early nineteenth century, product of the Enlightenment critique of the old customs of the *ancien régime*, though also of spadework in the exposition of civil law partly achieved under the aegis of late legal rationalism. After the Code Napoléon, promulgated in France in 1804, there followed a century of codification and legislative modernization of law in many places, and with this characteristically went approaches in legal philosophy that stress the essential emergence of law from a sovereign's will, or the will of the state as a rational association (in Hegelian vein; see Hegelianism). Nevertheless, this movement produced its own counter-movements, stressing the importance of the spirit of the people as the basis of law (see Savigny, F.K. von; Bryce, J.; Jurisprudence, historical), or more prosaically locating it primarily in custom, a view particularly popular in the context of the common law (see Common law; Selden, J.).

Twentieth-century critics of classical positivism accuse its authors of confusing 'commands' with 'binding commands' (see Kelsen, H.; compare Weyr, F.) or of mislocating the roots of legislative authority in mere 'habit', rather than in the 'internal point of view' of those for whom the system within which authority is exercised has normative force (see Hart, H.L.A.). The Kelsenian version of positivism rests it on the necessary presuppositions for a value-free science of law, and other thinkers have pursued further the question of 'legal science' (see Bobbio, N.); the Hartian version rests it on the customs of at least the official and political classes in a state, whose practices concerning the recognition of certain criteria for the validity of legal rules define the ultimate 'living constitution' of a state, its 'rule of recognition' (see Legal positivism).

A notable offshoot of or development from positivistic legal study has been the development of ever-more rigorous approaches to conceptual analysis (see Legal concepts) and categorization, seeking to account for the use of concepts like 'duty', 'right', 'ownership' and others in the framework of general legal norms (see Norms, legal). Hohfeld's analysis of 'fundamental legal conceptions' (see Hohfeld, W.N.) has had many followers and critics, and contemporaries in other traditions have taken a somewhat more psychologistic approach to the task (compare Petrażycki, L.). Reflection on legal concepts as institutions or 'institutional facts' has led to developing an 'institutional' theory of law that transforms what was originally a naturalistic conception into a positivistic one (see Institutionalism in law; Weinberger, O.).

4 Laws and values

One way or another, whether in voluntaristic versions or in those that place more weight on customary or institutional aspects of law, nearly all forms of or approaches to legal positivism have insisted on the strong value-relevance of positive law. The matter of doubt has not been 'ought laws to be just?', but whether their being just is a condition of their being genuinely legal. The 'scientific' character of pure legal analysis has indeed been contrasted with the exercise of moral judgment or moral sentiment, or the engaging in ideological argumentation, that is involved in the critique of law as unjust or otherwise unsatisfactory from the viewpoint of human needs and aspirations. Some, however, have thought that critique itself can have a scientific or at least an objective basis, grounded in the fundamentals of human nature. Classical utilitarianism and nineteenth-century law reform are a case already noted; they had successors in the 'jurisprudence of interests' (see Jhering, R. von; Pound, R.), and, albeit with certain qualifications, in the later twentieth-century 'economic analysis of law' (see Law, economic approach to).

The need to subject law to critique is obvious from many points of view, none more urgently than that which takes note of the burdensome impact of legal sanctions on human happiness and liberty. If laws characteristically carry punishments for their infraction, some theory to justify penal institutions is called for (see Crime and punishment). Whether there are any abstractly stateable limits to the legitimacy of interference with liberty through legal

intervention has been another heated debate (see Law and morality).

Nevertheless, the positivists' claim that they can combine an a-moralistic conceptual analysis of law and its institutions with a readiness for critique of actual laws on moral and political grounds, and with a last-resort readiness to disobey or defy the law when it is unjust to an extreme, has been doubted by some. Gustav Radbruch felt himself driven by his experience of the Nazi years (and also, perhaps, by the implications of the radical voluntarism of Carl Schmitt) to abandon such a claim and to insist on a conceptually necessary minimum of basic justice in anything we can recognize as 'law' at all. The interpenetration of equity with law, and the interweaving of ideas of justice, equity and law, can be taken to point to a similar moral (see Justice, equity and law), and idealistic approaches to legal theory give a deeper grounding for such an approach (see Legal idealism).

5 Law as politics

However one takes one's stand on will against reason, or on natural law against legal positivism, most of the theoretical approaches so far considered give some way of accounting for the independent existence of law as a distinct social phenomenon. Law's independence, at least when underpinned by an independent judiciary, has been held to promise the possibility of effective control over arbitrary state action while at the same time guaranteeing at least the justice of formal equality to citizens and the degree of predictability allegedly desired by modern rational subjects. Here we have the 'rule of law' ideal that demands government under the forms of law and law in the form of clearly identifiable rules (see Rule of law (Rechtsstaat); compare Dicey, A.V.; Fuller, L.L.). Yet the mere existence of some body of sacred or secular texts embodying rules of law is not enough for any socially realistic account of law, or for any politically persuasive vision of the rule of law (see Social theory and law; compare Millar, J; Renner, K.). The statute book is not self-applying or self-interpreting (compare Wróblewski, J.). To secure the rule of law it is necessary to have prospective rules published to all. But, as L.L. Fuller points out, it is necessary that they be interpreted in a reasonable and purposive way, and faithfully carried into action by the officials of the state whose rules they are. How is this to be secured?

Many schools of thought, chief among them the realists (see Legal realism) in Europe (see Olivecrona, K.; Ross, A.) and in the USA (see Holmes, O.W., Jr; Llewellyn, K.N.; Frank, J.), have stressed the widely discretionary character of legal interpretation, both in relation to the general rules of the law, and in relation to the categorization of fact-situations as subsumable under the law for one purpose or another. On inspection, 'facts' can turn out as elusive as 'laws', and the study of legal processes of proof assumes a certain urgency (see Legal evidence and inference). All in all, it is a serious and difficult question to discern what, if anything, can render decisions reasonably 'reckonable' given the broad discretion vested in those who interpret the law.

One form of response has been to find that law is reckonable not on the basis of the official rules and standard doctrine, but rather on the basis of the 'situation sense' of a judiciary with a common understanding of political and policy objectives underlying law. These insights of the 'realists' have been carried forward more boldly by contemporary feminist jurisprudence, one version of which finds social prejudice directing law through the biases of judges. Another version locates an inner masculinity in the legal rules themselves, even and especially at their most abstract; the asserted values of objectivity and impersonality ultimately come under question as presumptions of doubtful desirability (see Feminist jurisprudence).

Within more mainstream jurisprudence the developed response to realism has been to work out extended theories of the rule of law, acknowledging that law is more than positive rules but arguing for the existence of other mechanisms within law controlling the role of substantive elements in decision-making (see Legal reasoning and interpretation). Such responses find a certain coherence within law, but by contrast the more developed critical (including critical feminist) approaches argue that there are central fractures and fault lines within the law, reflecting ultimately competing political visions of human association, often summed up as individualism versus community-values (see Critical Legal Studies). Ronald Dworkin's argument for coherence and integrity in law evokes the idea of an interpretive community, but seems too readily to assume that for any actual legal order there can be found a single consensual interpretive project, even in principle (see Dworkin, R.; compare Legal hermeneutics).

Taking an overall view, the project of establishing the rule of law as an independent base for the critique and control of state action is put in serious doubt, since interpretation is through-and-through political; and appeals to

the rule of law can themselves be moves in a political game, expressions of ideology rather than of higher values. It may be that in the end legal philosophy is faced, today as at its beginnings, with this dilemma: either legal reasoning and moral reasoning have that kind of in-principle objectivity proposed by natural law theory in its rationalist versions, or the theatre of law is simply a theatre presenting endlessly the power-play of rival wills and visions of the good. Many have sought a third way, not yet with acknowledged success.

Law, William (1686-1761)

William Law is popularly known for a single devotional work, A Serious Call to a Devout and Holy Life (1728), but was the author of seventeen other treatises concerned with many of the philosophical and theological issues of the earlier eighteenth century in England. Early on he embraced the thought of Nicolas Malebranche, and later the mystical philosophy of Jakob Boehme. Law's methodology is an awkward mixture of these influences, for he wanted to find reason in the 'creaturely Spirit' of the natural life (The Spirit of Love, 1752). He seems finally to have abandoned reason in favour of Boehme's 'metaphysical scheme', which enables him to discover meaning and coherence in a post-Enlightenment world.

William Law lived mostly in King's Cliffe, Northamptonshire, where he was born and died. He studied at Emmanuel College, Cambridge, where he was elected a fellow in 1711, but resigned this position in 1716, being unable to take the oath of allegiance to the Hanoverian George I. He was thus one of the 'nonjurors', who believed that the Stuarts were by Divine Right the legitimate monarchs of England and consequently true heads of the Church. Accordingly deprived of his college fellowship, he passed the next years variously in study and writing and as a tutor in the Gibbon household at Putney, Surrey, where he instructed the father of the great historian. About 1740, he retired to King's Cliffe at the invitation of Hester Gibbon, the historian's aunt, and one Mrs Hutcheson. Together they formed a kind of religious community, and in these circumstances Law, who never married, continued his reflective and orderly life to the end.

Law's writing is often polemical. *Three Letters to the Bishop of Bangor* (Benjamin Hoadly) his first work, written between 1717 and 1719, was a defence of the apostolic succession of bishops, in which he asserts the spiritual authority of the Church against an Erastian prelate who urged the ecclesiastical supremacy of the state (1762, 1:15). Later Law attacked Bernard Mandeville's *Fable of the Bees* (1714), lamenting 'the miserable Fruits of *Free-thinking*, which…tend not only to set us loose from the Regards of Religion, but to destroy whatever is reasonable, decent, or comely in human Nature' ([1723] 1762: vol. 2, 49) (see Mandeville, B.). Rather belatedly, Law joined the attack on the Restoration theatre in *Absolute Unlawfulness of the Stage-Entertainment fully Demonstrated* (1726). In his work Law argues persistently for right action. Laid out in terms of lively vignettes of persons who live frivolous or arid or else pious lives, his *Serious Call to a Devout and Holy Life* (1728) provides a systematic plan for ordering one's moral and devotional life.

Given Law's devotion to the reasonable spiritual life, his development of a mystical theology may seem curious, yet he believed he was recovering deeply felt, if elusive, truths. Never systematic, Law's philosophical ideas are expressed in generalities and his theological views often lead to untraditional conclusions. From 1740 onwards, he gave himself over to the study of Jakob Boehme, and his later writing, especially *The Spirit of Prayer* (1749) and *The Spirit of Love* (1752), is filled with a sense of cosmic goodness. The later style may be well suited to its subject; but it is the plain and straightforward Law of *A Serious Call* that Dr Samuel Johnson pronounced 'the finest piece of hortatory theology in any language' (Boswell 1791: vol. 1, 390).

Laws, natural

It is widely supposed that science aims to identify 'natural laws'. But what are laws of nature? How, if at all, do statements of laws differ from 'mere' general truths which include generalizations true only 'accidentally'? Suppose, for example, it happens to be true that all iron spheres (past, present and future) are less than 1 km in diameter. Contrast this with the truth of 'all electrons are negatively charged'. There seems to be a clear intuitive distinction between these two truths, but is there any principled distinction between them that can be drawn and defended?

This has been the traditional focus of philosophical attention concerning laws of nature, and basically two mutually opposed philosophical accounts have been developed. According to the first account, there are real necessities in nature, over and above the regularities that they allegedly produce (whether or not these regularities are held to be observable), and law-statements are descriptions of these necessities. According to the second account, there are no necessities but only regularities (correlations, patterns) and laws are descriptions of regularities (though perhaps not of any regularity but only of the most basic or most general ones). There are significantly different variants of each account; and also positions that altogether deny the existence of general laws (or deny that science should aim to describe them).

Any one of these accounts, if it is ultimately to be coherent and defensible, has to successfully address four interrelated issues: the meaning of a law statement - the semantic issue; the fact to which a law statement refers and which makes it true - the metaphysical issue; the basis on which claims to know a law are justified - the epistemological issue; the capacity to explain adequately the variety and roles of scientific laws - the explanatory issue.

In attempting this task, each of the available accounts faces its own distinct difficulties. For example, if there are necessities in nature, as the first account claims, how exactly do we identify them: how can we tell which of the inductively confirmed regularities are laws? On the other hand, if there are only regularities, as the second account claims, does this mean that our intuitions and scientific practices are awry and that there really is no distinction between laws and accidental generalizations?

The difficulties facing all extant accounts become even more marked when we face up squarely to the surprisingly wide variety of (putative) laws supplied by current science and to the complexity of the relations between those putative laws and regularities and causes.

1 Laws in science

Science exhibits a diversity of kinds of law (law statements). Causal laws specify succession: B causally follows A in time; sunlight causes sunburn (see Causation). Laws of synchronic coexistence specify atemporal relationships: for a gas at equilibrium, temperature equals pressure times volume (in suitable measurement units). Basic structural laws specify the fundamental principles defining a theory framework: spacetime world lines of individuals neither intersect nor branch (that is, no two things can be at the same place at the same time and nothing can be at two places at once). Derived structural laws are laws of diachronic coexistence, A at time $t1 = A$ at time t2: energy is conserved in an isolated system. Functional-analysis laws connect functional capacities of complex systems: teleological systems require negative feedback to maintain goal orientation.

Some laws are inclusionary: all electrons have charge e; some are exclusionary: nothing travels faster than the speed of light *in vacuo*. Some laws are deterministic: $f = ma$, Newton's second law of motion, while others are statistical: given an incident UV photon, a skin cell has probability P of dying (see Determinism and indeterminism; Probability, interpretations of). Some laws interrelate localized individuals (for example, the gas coexistence law above, $PV = T$), others concern field states (for example, the superposition principle, which has no equivalent among individuals). Symmetries, that is, invariance constraints, ground derived structural laws and may lie behind causal laws (quantum field theories) (see Conservation principles; Field theory, quantum).

There is no single or simple relationship of laws to causes (of law statements to causal statements). The causal gravitational action of the sun directly produces the planetary motions, but while causal collision processes are ultimately responsible for gas behaviour only their statistically average behaviour at equilibrium is captured in the

constraint $PV = T$. Many laws, for example that all ravens are black, are the end product of many interacting causes (constrained by specific initial conditions). Some macroscopic succession laws cannot, at present, be clearly understood theoretically as being the result of interacting microscopic causes (for example the second law of thermodynamics, because in current theory the thermodynamic, but not the microscopic dynamic, law is time-irreversible - see Thermodynamics). Some laws derive from the inoperativeness of causes (the conservation laws); others have no simple relation to causes (for example, structural laws, the quantum Pauli exclusion principle).

Nor is there any single or simple relationship between laws and regularities (between law statements and descriptions of regularities). Kepler’s laws of planetary motion specify simple, if empirically approximate, regularities. Newton’s first law of motion, given the gravitation law, is empirically never instantiated and so has no directly associated regularities, but does specify a higher-order regularity of convergence on first-law behaviour as system forces decrease. There is evidently no analytic solution to the Newtonian gravitational three-body problem, so there is no easily specified associated empirical regularity; yet the earth-moon-sun system exhibits a solution. Statistical relationships do not directly issue in any particular empirical regularities, only in approximate higher-order ones (laws of large numbers). Further, a nonlinear system showing chaos will never repeat its sequence of states, yet its dynamics is law-governed, indeed deterministic (see Chaos theory). Here again there is no useful logical formula that describes the dynamic pattern (as a pattern); we can only explore it through computational approximation from the generating equations. Thus evolution and history might show no repeated patterns, yet unfold according to some very complex (largely unknown) nonlinear dynamic laws.

Conversely, empirical regularities have diverse relations to laws. Consider two clocks exhibiting a regular connection between the readings on their two faces. This regularity may arise from (a) a direct physical connection between them whereby the face reading of one sets (causes) the face reading of the other; (b) an immediate common cause, a single human setting both clocks to the same time; (c) a mediate common cause, two separate people separately setting their clocks to the same socially shared time, ultimately generated from a common standard clock; (d) two mutually independent random quantum events initially coincidentally setting the clocks to the same time; (e) at each second the two clocks coincidentally resetting to the same times as in (d).

There are laws (law statements) referring to (i) real systems (for example, Newton’s second law of motion), (ii) idealized systems which could not be real but which approximate real systems in some respect (for example ’ $PV = T$’, which assumes a gas of point particles - see Fictionalism; Idealizations; Models), (iii) systems which could be real but are never instantiated (for example, Newton’s first law, given gravitation), or only approximately instantiated (Kepler’s laws in our solar system). Groups (ii) and (iii) nonetheless both render the mathematical structure of the corresponding natural laws simpler and exhibit the structure of component causes (for example, forces).

Within the explanatory issue, then, call achieving a coherent account of the diversity of kinds of law the ’diversity problem’, understanding the complex relations of laws to regularities the ’pattern problem’ and understanding the diverse roles of idealization in laws the ’idealization problem’. Philosophical theories of science have often ignored or simplified the distinctions among, and rich diversity of, scientific laws; a good philosophical account of natural laws would itself bring order into these complexities.

Scientists use laws to explain both other (’less basic’) laws and particular events (see Explanation §1), to deduce what will happen (predict) and what would have happened had (counter-factually) circumstances been different, to separate complex causes into their components and to distinguish between accidental and law-based empirical regularities, to decide when experimental and inductive inference procedures are justified (see Confirmation theory §1; Experiment; Inductive inference §4), to decide what basic properties there are, and so on. An account of the role of laws is thus central to a philosophical account of science. Call providing such an account the ’roles problem’.

In sum, the explanatory issue comprises the diversity, pattern, idealization and roles problems. Responses are based on coordinated proposals for the semantic, metaphysical and epistemological issues.

2 Two philosophical accounts

Necessitarian theories. We make sense of our experience both through introducing causes which produce or

necessitate their effects, and through counter-factual reasoning about possible though not actual cases governed by laws which still continue to constrain what is possible. These are the intuitive sources of necessitarian accounts, which introduce a metaphysics of necessary connections as truthmaking conditions for law statements.

Proponents of nonlogical necessitarian theories - developed earlier this century by Johnson, Kneale and von Wright, among others - hold that both laws and true accidental regularities are confirmed by factual observation, so are in that sense contingent, but the law 'all A are B' also rules out the possibility of a non-B A, in analogy to the laws of logic specifying the logically possible. The view that laws do possess logical necessity - noncontingent, logical necessitarianism - was defended earlier this century within the idealist rationalist tradition, including Blanshard,Ewing and Stout. Recently versions have been revived of both nonlogical necessitarianism, for example Armstrong (1983), and logical necessitarianism, Swoyer (1982).

The central metaphysical problem is to characterize necessity. Is it (i) an object or (ii) a relation? Does it connect (a) objects or (b) properties, powers dispositions? There is a traditional objection to (i): how can adding an object create a necessary connection? (Notice, however, that quantum theory represents forces as something like exchange of special objects, bosons.) There is a traditional objection to (ii): it involves developing a metaphysics of real universals (properties, powers, or dispositions) but this is implausible/incoherent. Will statistical laws require the postulation of special propensities as their truthmakers, and what are these? Would basic negative laws require real negative universals? Would uninstantiated and idealized laws require unactualized and idealized universals? Arbitrary positive answers trivialize this approach; but what principled basis for response is there? (These cases are also troubling for version (i).)

The necessitarian semantic problem is to provide a meaning for law statements that renders them logically stronger than statements of regularity. Though there are many modal logics, it is controversial whether the truth conditions of their statements identify appropriate natural necessities. It has proved similarly difficult to construct a satisfying logic of counterfactual conditionals, which natural necessities distinctively support, and it is controversial whether agreement on a satisfactory formal theory could do more than describe proper inferential practice, assuming natural necessities somehow otherwise identified (see Counterfactual conditionals).

The central necessitarian epistemological problem is that of identifying necessities: how to tell which among inductively confirmed regularities are laws? Any principle that would render inferences from evidence to laws deductively valid (for example that nature is finite and causally uniform) must itself be justified in the same way (vicious circularity) and arguably there are no observable necessitating connections. David Hume drew the sceptical conclusion that no claim to know which evidentially confirmed regularities are laws is ever justified, our scientific knowledge being confined to affirming past regularities and relying on them out of 'habit', without rational warrant. Appeal to some scientific methodology *per se* does not alleviate this problem.

Eliminative necessitarians respond by retaining necessitarianism while dismissing laws as part of the metaphysics of science. Cartwright (1983) argues that laws are so idealized and indirectly related to empirical phenomena that they cannot be regarded as real, while individual causes are real and the basis for scientific reasoning. Eliminationism faces its own difficulties with the metaphysical and semantic issues, but especially with the epistemic and explanatory issues, since it must show how scientific practice can be properly understood without effective recourse to laws, while simultaneously identifying and using causes.

Regularity theories. Historically, objections to necessitarianism, especially epistemological objections, have motivated the development of regularity theories of laws. According to these theories, laws in nature are nothing more than matter-of-fact correlated event patterns. There is no metaphysical distinction between accidental and lawful regularities. The law-likeness of accepted scientific generalizations describing these patterns is at best organizational, a matter of our attitude to, or use of, these statements as 'inference licenses' (Lange 1993), which support habitual, because pragmatically useful, practices of induction, prediction and counter-factual reasoning. Often law-like status is held to be determined by depth of entrenchment in science - (roughly) the wider the generalization, the deeper its entrenchment and the more law-like its accorded status.

The contingent, nonlogical regularity version is the simplest, most common one and its supporters include Braithwaite (1953) and Hesse (1980) among many. It has no need for special necessities in nature, and avoids special semantics for law statements by making the simple logical form ' $(x)(Ax \rightarrow Bx)$' the universal paradigm.

Conversely, however, it is difficult to provide an account of our practices of counterfactual inference since, given '-A*a*', ' $(x)(Ax \rightarrow Bx)$' is vacuously instantiated independently of whether or not 'B*a*' holds. It is also difficult to explain how there can be uninstantiated laws, whether or not pertaining to idealized entities, since all uninstantiated extensional conditional statements are vacuously true. More generally, it is difficult to see how a simple regularitiy account could explain the complex relationship between laws and empirical regularities; regularities are neither necessary nor sufficient for laws.

In the light of the difficulties facing nonlogical regularity theories, some philosophers sought to retain their metaphysical simplicity by adopting instead the view that laws are contentless conventions, linguistic meaning definitions, and necessarily true on that account. They were held to be pragmatically useful in the organization of empirical information, in roughly the way that any other linguistic practice is, but no more. Earlier Poincaré, Mach and Reichenbach defended versions of this noncontingent, logical regularity view and later conventionalist debates echo them (see Conventionalism). This theory provides a sense of necessity to laws compatible with a regularity metaphysics, but only at the cost of eliminating their empirical content. It is then hard to explain the content of scientific theories and hence also to make sense of scientific method. How can we explain why laws are so useful, and when they are useful, if they are only conventional definitions? Why should they ever be changed? Why are there so often no viable scientific alternatives to a theory, if alternatives are created merely by linguistic redefinition?

Another, opposite, reaction to the same difficulties is to retain empiricism while dismissing laws as of no significance to an account of science; this is eliminative regularity theory. Van Fraassen (1989) argues that scientific theories are concerned with symmetry and continuity, not universality or necessity. His view is that laws are anachronisms, remains of an early modern necessitarian essentialist metaphysics, and not something at which science can, or should, aim. He recognizes the importance of theory in science but, pursuing empiricism, construes it largely pragmatically rather than realistically, rejecting all postulated modal connections as unwarranted metaphysics. While this view faces its own problems in responding to the metaphysical, semantic and epistemological issues, special interest attaches to the explanatory issue, since eliminativism needs to show how scientific practice can be properly understood without effective recourse to laws.

3 A note on laws and logical analysis

Philosophy of science in the twentieth century has been dominated by the analytic tradition deriving from logical empiricism and Frege-Hilbert-Russell logical analysis (see Analytical philosophy §2). This tradition emphasizes syntactical logical form, and analysis as the basic tool of philosophical inquiry. In these terms, the traditional issues surrounding natural law have been: (A) What is the syntactical logical form of law statements? (B) What distinction in logical form demarcates (statements of) laws from accidental regularities? These questions have not received satisfactory answers. For example, it has generally been held that law statements have at least to be unrestricted universal claims of the form 'all A are B'. But this claim is either substantive and false, for example statistical laws are not perspicuously of this form, having instead such forms as 'probability (B, given A) = P', or it is true but uninformatively weak, since nothing is excluded (even statistical, idiosyncratic and accidental relationships can still be forced into this form). Many philosophers, representing otherwise opposing positions about laws, now reject this syntactic search as the vehicle for addressing the semantic issue, treating the semantic structure as primary; for example Suppe (1989).

Formal analysis, whether syntactic and/or semantic, continues to be applied to other related problems. The idea of accidentality, for example, may be explicated (Popper 1990) as that of logical dependence on initial conditions (in some theory): the more condition-dependent a statement is, the relatively more accidental it will be (Sklar 1990). And the idea of entrenchment has been formally elaborated in various ways. For example, according to Piaget one does not have a natural law until it specifies a true pattern that is demonstrably (that is, mathematico-logically) complete, the ultimate laws of science being those of logic and mathematics themselves. Others attribute law-likeness only to science satisfying certain conditions, for example to the system of scientific truths having the best combination of simplicity and informativeness (Lewis 1973). Galileo's law of free fall by itself would not count in either case, but Newton's laws of motion plus gravitation plausibly would.

Here also belong analyses of law-likeness in terms of probability, subjective (Skyrms 1980; Urbach 1988) and objective (Mellor 1990), along with other formal analyses aimed at transcending various distinctions (Mormann

1994).

All of these, and the many other, formal analyses are mutually conflicting and highly controversial. Their relations to the competing regularity and necessitarian positions depends on exactly how they are developed. (Lewis and Popper, for example, claim to combine possible worlds semantics for necessity with regularity theory.)

4 Conclusion

The existence and nature of laws is a complex problem. The diversity of philosophical theories in response is matched only by the diversity of laws themselves. The reader will find many further themes recurring in the literature - for example: the analysis and status of possibility and possible worlds; laws and initial/boundary conditions; causes, capacities and laws; concepts, laws and generality - which cannot be pursued here. There is no uncontroversial theory of laws: all face difficulties. As fast as we scientifically unravel nature’s mysteries, so fast does the nature of that understanding become mysterious.

Le Clerc, Jean (1657-1737)

Le Clerc was not a particularly original philosopher - his position was somewhat eclectic - but his journals and textbooks make him an important historical figure. He acted as an intermediary between English and Continental traditions. In religion he advocated an attitude of toleration.

The Swiss thinker Jean Le Clerc (Johannes Clericus) was born in Geneva. After his theological studies there he travelled extensively in Europe, read Spinoza and started a correspondence with the Remonstrant theologian Philippus van Limborch. In 1683 he settled permanently in Amsterdam where he became a minister of the Remonstrant Brotherhood and was given a chair in philosophy at their seminary. In 1686 he started the journal *Bibliothèque Universelle* (25 vols), which in 1703 was followed by the *Bibliothèque Choisie* (26 vols) and in 1714 by the *Bibliothèque ancienne et moderne* (29 vols). These journals were instrumental in spawning debates which involved, among others, Leibniz and Bayle. They also were a channel for the spread of English ideas to the Continent, where people learned about Locke, the Cambridge Platonists, Berkeley and others by reading Le Clerc's abstracts (see Cambridge Platonism). Le Clerc edited the collected works of Erasmus and a work of Hugo Grotius (*De veritate religionis christianae*, 1709). His correspondence testifies to his friendship with numerous famous contemporaries.

Le Clerc was familiar with the philosophy of Descartes from his studies in Geneva with Robert Chouet. But although in physics and in metaphysics he remained basically Cartesian all his life, Cartesianism was never for him a closed system of thought. He not only modified and corrected Descartes' ideas in the light of Locke, Boyle and Newton, but was also influenced by the Platonism of Cudworth. Thus, we see him taking issue with Descartes on topics such as the existence of innate ideas (which he rejects) and animal machines (he attributed to animals some power of thinking). He was fascinated by Cudworth's theory of 'plastic natures' - which he publicized in his journals - because he believed that they provide a better explanation of the formation of animal organisms than the one-dimensional mechanism he found in Descartes. He remained a metaphysical dualist, however, and also believed that a consistent application of Descartes' principles (more consistent at any rate than we find in Descartes himself) is of very great use in establishing the truth of the Christian religion.

According to Le Clerc, religion does not require us to abandon our reason: we can never deceive reason, nor can reason ever deceive us. Accordingly, there is fundamental agreement between reason and revelation, not in the sense that revelation can ever be replaced by reason, but rather that the right use of reason leads us to accept revelation and that revelation in turn is never contrary to reason. In religion, Le Clerc's attitude was formed by Erasmus and Grotius. He believed in the value of philosophical and critical methods in theology and was an advocate of tolerance. His opposition to 'enthusiasm' (his reason for rejecting Malebranche) and 'fanaticism' had much influence on English Latitudinarians.

Le Doeuff, Michèle (1948-)

Michèle le Doeuff has created new possibilities for philosophical writing. By working between philosophy and Shakespearean drama, social history and personal letters, she demonstrates how philosophy's concepts gather meaning by circulating between different forms of discourse. In so doing she takes up many of the main problems of philosophy, including the nature of the self, the possibility of philosophical ethics, and the place of women in society and in philosophy. She shows, too, how philosophy's proper commitment to critical reasoning represses the role of imagery in its own creative thought; philosophy seems dedicated to achieving theoretical results beyond its means, and imagery is misused to disguise its inevitable incompleteness. The spectre of women, or of some other group typified as 'irrational' is used to reassure philosophy of its own integral rationality.

Michèle le Doeuff has been employed as a philosopher at the École Normale Supérieure de Fontenay, the Centre National de la Recherche Scientifique in Paris and (1995) the University of Geneva. Her work generated discussion internationally after the publication in English in 1977 of 'Women and Philosophy' and, in 1979, of 'Operative Philosophy'. A study of the role of imagery in philosophy and science, *Recherches sur l'imaginaire philosophique* (1981) (*The Philosophical Imaginary*, 1989) was followed by translations and studies, first of Bacon's *New Atlantis* (1983b) and then of Shakespeare's *Venus and Adonis* (1986). Her most extended work, *L'Étude et le rouet* (1989) (*Hipparchia's Choice*, 1991), written as four 'Notebooks', interweaves semi-fictional and historical anecdote, comment on the nature of philosophy, critical analysis of existentialism, and reflection upon philosophical biography and the philosophical 'subject'.

Le Doeuff exposes the male bias in the images, anecdotes and theory of Sartrean existentialism, and expresses critical astonishment at de Beauvoir's *tour de force* in adapting this system for her analysis of the position of women in *The Second Sex* (see Beauvoir, S. de). She claims that de Beauvoir placed her feminism within a structure of ideas which is itself an epitome of the male fear of women. Le Doeuff emphasizes the imagery which Sartre uses in *Being and Nothingness* to connect the female body with ontological 'lack' and the threat posed by matter generally, to 'masculine' free consciousness. In *The Philosophical Imaginary* le Doeuff develops a strategy of analysing philosophy at the 'neuralgic points' signalled by its imagery. Kant, for example, writes of 'Truth' in terms of the image of a northern island separated by a stormy ocean from the southern islands of illusion where duty and pleasure can coexist. Le Doeuff characterizes Kant's rhetorical image as a classic form of parental threat and seduction. His efforts to set limits to metaphysical speculation only indicate how much lies beyond that limit to be cordonned off.

Le Doeuff's theme of the role of utopias in philosophical enterprise connects with her use of imagery in analysing the partial blindness any theory has to its own level of operation. More's *Utopia*, for instance, is not only a political ideal, but a trope of the ideal life of the individual scholar who desires a world in which nothing disturbs his inner peace. The figure of Utopus, the island whose life is reflected in its internal harbour of still water, represents the triumph of tranquil private enjoyment as an ideal life for its citizens. It is this dream of a political system in which narcissists could cooperate enough to meet their material needs which lies behind More's criticism of existing political institutions. More's political vision is argued to spring from a too limited idea of pleasure, and of what people can gain from and with each other. Le Doeuff pays similar attention to 'voice' in philosophy, showing how voice, too, operates vitally even in writing which affects to be free of affect. While being critical of the operation of voice, philosophers must accept and use it, rather than merely deploring it as an 'irrational' element in discourse.

Le Doeuff's work stresses this need for a complex attitude towards elements which help create philosophy and yet threaten its attempt at being reasonable. 'Masculinist' and 'logocentric' assumptions have been endemic in the production of philosophy and yet it is no use, she maintains, for women to attempt to redress the situation by expressing a special 'femininity' in philosophy. That femininity is a fantasy conjured up by a 'masculinity' bent on arrogating the field of reason to itself. At the same time, le Doeuff attacks the pretensions of 'masculinism' by all available means of argument and satire. Her critique of philosophy is not that it practises some excess of reason. It exhibits too *little* reason. In the name of a higher, or benignly legislative devotion to Reason, it has defined its own integrity by excluding women, or people of 'inferior' cultures, or children, as constitutionally on the other side of

Reason. It is not philosophy's ideal of being logical which does the harm. Rather it is 'logocentrism', by which le Doeuff means the hardy tendency of philosophers to 'form projects beyond philosophy's means' by aiming at one 'logos' - one account of things to legitimate all other forms of discourse. A philosophy prepared to interact with the verbal interjections of unregularized 12-year-olds, she observes, 'may be a form…that no longer considers its incompleteness a tragedy' (1989: 126).

Le Doeuff's study of the operation of imagery in philosophy leads on to a concern with various images of the natural and the philosophical 'subject'. Though scathing of Husserl's inflated agenda for re-establishing philosophy on the basis of a 'transcendental ego', she sees the trick of transcendence - the illusion of being master of everything which is consciously intimate to us - as natural to human thought. Le Doeuff does not present a *theory* of the subject in one of the standard styles of idealism, dualism or materialism. Rather, borrowing from the tradition of phenomenology whose conclusions she repudiates, she looks into the natural origins of the fantasies such excessive theories articulate. Analysis of philosophical theory is set beside studies of the speeches of Shakespearean characters in which, humorously or tragically, they engage in the fantasy of transcending their 'empirical specificities'. She shows how the narrative voice constructed by a Descartes, a Husserl or a Sartre, becomes transformed into a 'mind distinct from a body', a 'transcendental ego', or a 'totally free consciousness'.

Le Grand, Antoine (1629-99)

Le Grand was the foremost expositor and popularizer of Cartesian philosophy in England during the seventeenth century. He wrote on ethics, politics, logic and numerous scientific topics. His Cartesian system is one of the most complete, emphasizing mind-body dualism and interaction, innate ideas, mechanism and method. His theory of signification is important in the Cartesian debate on ideas.

Born in France at Douai, Antoine Le Grand was sent as a Franciscan missionary to England where he spent most of his life, spreading Cartesian philosophy. He was well received by the Neoplatonists at Cambridge, but not so at Oxford where Cartesian philosophy was banned.

Le Grand's early writings are not principally Cartesian. In *Le sage des Stoiques ou l'homme sans passions* (*Man without Passion*) (1662) he expounds the doctrines of the late Stoic, Seneca: the principles of the passions are useless to virtue, and thus a wise man ought to live without passion. However, Le Grand later rejected this position because, like Descartes, he came to view the passions as conducive to life in their preservation of the mind-body union. In his main political work, *Scydromedia* (1669), he depicts the ideal state as one whose dominant features include autocracy limited by law, open trade, private property, education of the youth and religious unity.

Le Grand's comprehensive *Institutio philosophiae* (*An Entire Body of Philosophy*) (1672) includes applications of Cartesian principles of the sort that Descartes had only envisaged, with discourses on insects, plants, natural theology and ethics, plus expositions of many traditional Cartesian topics such as the *Cogito*, innate ideas and proofs of God's existence. Consistently anti-Aristotelian, Le Grand substitutes Cartesian principles of method for those found in ancient and scholastic logic. He rejects the law of non-contradiction as a first principle because it presupposes that something exists, and thus is dubitable. In the Cartesian order of philosophizing, first truths must be indubitable propositions; since the *Cogito* presupposes nothing, it is indubitable and hence a first principle. Similarly, Le Grand replaces Aristotelian form and matter with Cartesian substance and mode.

Le Grand defends Descartes' account of ideas as representational modes of the mind. The nature of ideas was a topic greatly debated in the latter half of the seventeenth century. A crux of the debate was to explain how ideas which do not resemble their objects can represent them. Le Grand's contribution was to explicate the subject (idea)-object relation in terms of signification: ideas are signs that acquire signification by a causal process ultimately dependent on God's will.

Like a minority of his Cartesian contemporaries, such as Desgabets and Régis, Le Grand retains the interaction of mind and body while rejecting any occasionalist solution to the problem of how two essentially different substances causally interact. Additionally, Le Grand defends Descartes' doctrine of the free creation of eternal truths - that God created all things in their essence and their existence. Malebranche argued that this doctrine undermines the a priori basis for knowledge, although Le Grand never drew this consequence.

Against the traditional Aristotelian account of soul, Le Grand defends the Cartesian 'beast-machine' doctrine that non-human animals lack souls and hence are subjects for purely mechanical explanations. The animal soul is essentially corporeal, unlike the human soul which is essentially thinking and incorporeal. Thus the mechanizing of the sensitive soul is achieved without abandoning a spiritual account of the rational soul.

Le Grand was not an original thinker but he was instrumental in bringing Cartesian philosophy to a wide audience in England. He gave Cartesianism a scholastic form to aid its acceptance, and he was thoroughly loyal to Descartes' ideas, making him, uniquely, a complete Cartesian apologist.

Le Roy, Édouard Louis Emmanuel Julien (1870-1954)

Le Roy was a French mathematical physicist and Catholic modernist philosopher. Starting from a philosophy of life similar to Henri Bergson's philosophy of creative evolution, he argued that the capacity for invention was fundamental to human existence. This led him to develop a radical form of conventionalism according to which scientific facts are created rather than discovered. Henri Poincaré attacked this view, arguing that the scientist creates only the language in which facts are expressed.

Le Roy was born in Paris. His father was in the transatlantic shipping business, with his own outfitting company in Le Havre. Le Roy entered the École Normale Supérieure in 1892, passing the *agrégation* in 1895 and earning a doctorate of science in 1898. For many years, he taught mathematics at a Paris *lycée*. An assistant to Henri Bergson at the Collège de France from 1914 to 1920, he was named Bergson's successor in the chair of modern philosophy in 1921, and remained in that position until his retirement in 1941. In 1919 Le Roy was elected a member of the *Académie des Sciences Morales et Politiques*; in 1945 he succeeded Bergson as a member of the Académie Française.

Le Roy was a controversial representative of the Catholic modernist movement in France. He held a pragmatic view of religious dogma, whereby dogma has practical value as a source of moral directives in spite of its seeming inscrutability and incompatibility with positive, rational knowledge. These ideas, developed in such works as *Dogme et critique* (1906), earned Le Roy condemnation by Pope Pius X in an encyclical of 1907, and his *Le problème de Dieu* (1929) was put on the Index in 1931. At the centre of Le Roy's thinking is a vitalist philosophy of life and a spiritualist philosophy of freedom closely allied to Bergson's doctrine of creative evolution and similar in crucial respects to the ideas of Le Roy's friend, Teilhard de Chardin (see Bergson, H.-L.; Teilhard de Chardin, P.; Vitalism). The human capacity for invention is fundamental and points us back to the critical phenomenon of 'hominization', when the noosphere emerges from the biosphere. A free, self-creative human agent becomes the basis of Le Roy's mature moral philosophy and philosophy of religion, in which central roles are played by transcendence, a quest for self-fulfilment and respect for a generalized moral obligation and spiritual need arising out of the human vital spirit.

As with Bergson, intuition is for Le Roy the way to true knowledge, which consists in a non-discursive immediacy characteristic of the primitive, authentic relationship of instinctive life to its surroundings. All discursive knowledge, however, is invention. Such invention may be necessary in the form of practical rules as a guide for human action, but, as invention, discursive knowledge can make no more claim to truth than the arbitrary rules of a game. This idea, with its emphasis on the mediating role of the senses and conceptual forms, owes an acknowledged debt to the Neo-Kantianism of Émile Boutroux, but Le Roy made it the basis for a radical form of conventionalism that he first presented in a widely discussed article, 'Science et philosophie' (1899-1900) (see Conventionalism). Le Roy's point of view gained considerable notoriety when it became the subject of an extended critical discussion by Henri Poincaré in 'Sur la valeur objective des théories de physiques' (1902) (see Poincaré, J.H. §4). The challenge of Le Roy's more radical conventionalism led Poincaré to some valuable and essential clarifications of his own, more moderate, conventionalism. Two major points were at issue. First, Le Roy had argued that scientific facts are merely the artificial creations of the scientist, citing as examples the concept of the atom, the phenomenon of the eclipse and the rotation of the earth. Poincaré responded by doubting that one could distinguish crude facts and invented scientific facts as sharply as Le Roy might think possible and by insisting that crude facts themselves play a role in science by imposing scientific facts upon us. Poincaré grants the presence of a creative moment in science, but he confines it to the conventional choice of disguised definitions, as in the choice of a unit metre stick or the choice of Euclid's parallel postulate, choices analogous to the choice of a language. Once those conventions are accepted, the remaining propositions of science have a determinate truth-value ascertainable by empirical means. Moreover, the role of such arbitrary conventions diminishes steadily as we move from the basic levels of science, such as geometry and kinematics, to mechanics and physics. The second point of difference between Poincaré and Le Roy concerned the question whether, among the conventional variants of a given scientific theory, there remained any 'universal invariant', a content common to the different formulations. Poincaré interpreted Le Roy as denying the existence of such an invariant content, but himself insisted upon it. Arguing again by analogy with translation between two languages, such as French and German,

Poincaré held that one and the same proposition could be expressed equivalently in either language, with determinate rules of translation allowing us to go back and forth between the two.

In his *La théorie physique* (1906), Pierre Duhem declared his sympathy for Le Roy's conventionalism in opposition to Poincaré's critique (see Duhem, P.M.M. §4). Two years later, in *Identité et réalité* (1908), Émile Meyerson expressed sympathy for Le Roy's views, but identified himself more closely with what he regarded as the less radical position of Duhem. Le Roy's radical conventionalism had perhaps its most profound influence on Kazimierz Ajdukiewicz. By contrast, his work in the philosophy of mathematics, and his writings on microphysics and relativity theory, were of less lasting import.

Learning

Learning is the acquisition of some true belief or skill through experience. Rationalist/idealist philosophers held that the very constitution of thought guarantees that fundamental laws hold of the world we experience, and that our understanding of these laws was therefore innate, not learned. The empiricist tradition, doubtful of these Rationalist claims, denied that much was innate, and held that learning occurred through associations of mental representations. This view was lent support by the nineteenth-century development of physiological psychology, which led to a view of learning as a system of adjustments in a network without any intervening representations, a perspective that led in turn, in the twentieth century, to behaviourist studies of stimulus-response associations, and eventually to contemporary neural net computational models.

Empiricism, however, had also invited, especially with Hume, doubts that the correspondence between mental representations and the world could be known. Hume believed people learn, or at least form new habits, but he did not think there could be any normative theory of learning - any way of making it 'rational'. His scepticism led to the development by Bayes and other statisticians of formal theories of how learning from evidence ought to be done. However, the standards that developed in the form of the theory of subjective probability proved impossible to apply until very fast digital computers became available.

The digital computer in turn prompted both novel normative theories of learning not considered by the statistical tradition, and also attempts to describe human learning by computational procedures. At the same time, a revolution in linguistics held that humans have an innate, specialized algorithm for learning language. Applications of computation theory to learning led to an understanding of what computational systems - possibly including people - can and cannot reliably learn. Major issues remain concerning how people acquire the system of distinctions they use to describe the world, and how - and how well - they learn the causal structure of the everyday world.

1 Eighteenth- and nineteenth-century empiricism

The empiricist tradition, represented in the eighteenth and nineteenth centuries by Hume and Mill, among philosophers, and by Maudsley among psychologists, developed an associationist psychology in which mental dynamics is driven by 'associations' among 'ideas', roughly bits of images or propositional content. Associations were thought to be constituted both by internal relations among ideas - similarity, for example - and external physical relations - near simultaneity of acquisition, for example. The doctrine of ideas distinguished simples and compounds. Experience presents compound ideas (or 'impressions' from which ideas are formed) which are separated into simples by a kind of internal analysis (see Empiricism; Hume, D. §2; Mill, J.S. §§2, 3).

Empiricist psychology produced foundational problems: how such can such processes lead to faithful representations of the external world, and how can we know that they do? Hume argued that they could not be known to do so. The dominant alternative answers in the eighteenth and nineteenth (and, one might argue, twentieth) centuries were forms of idealism, from the phenomenalism of Mill and Mach, which held that all reality is appearance, to the transcendental idealism of the Kantians, who agreed with Hume that we cannot know the world 'in itself', but held that the very conditions for the possibility of thought and experience guarantee the fundamental geometric, temporal and causal structure of experience (see Idealism; Kant, I. §§4-6; Mach, E.; Phenomenalism).

Helmholtz read Kant as offering a (false) psychological theory rather than a logical solution to sceptical doubts about knowledge and the apparent phenomena of a prioricity. Helmholtz offered empirical analyses of the visual and auditory systems, emphasizing both their physiological mechanisms and the external conditions required for their reliability. His work represents perhaps the first really 'naturalized' epistemology, rejecting all a priori justifications of the reliability of human belief.

The network structure of the cortex, established by Cajal in the 1890s, gave new impetus to associationist theories of learning. In psychologists as varied as William James and Sigmund Freud, 'ideas' were vaguely and variously associated with states of particular cells or collections of cells, or with distributions of energy among cells. Learning was thought to be some process by which these systems were adjusted in response to inputs from sensory

transducers. The network idea offered at least the skeleton of a unified account of the acquisition of both behavioural and inferential skills. Under James' influence, Edward Thorndike called himself a 'connectionist' and network talk became (and remains) both a metaphor for associations, a detailed computational model, and a theory of brain function. In the first two roles, the strengths of the connections between network nodes have commonly been assumed to be modified either by their temporal pairing or by a feedback process sensitive to a discrepancy between the output of the system and a 'teaching' signal. This discrepancy (the error in the output) is fed back into the system that maps inputs to outputs, altering the connection strengths so as to reduce the discrepancy. In the behaviourist tradition (see Behaviourism, methodological and scientific), the first process for modifying the strengths of connections is called classical or Pavlovian conditioning, while the second is called instrumental or operant conditioning. In more recent 'neural net' computer simulations (see Connectionism), the first process is called 'unsupervised learning', while the second is called 'supervised learning', although no real neural process is known that corresponds to propagating errors back through a network.

2 Cognitive nature of the associative process

Thorndike is often regarded as one of the fathers of (scientific) behaviourism, the psychological movement that holds that psychology should focus exclusively on causal relations between 'stimuli' and behavioural 'responses'. One stimulus became associated with another, or with a response, as a result of 'reward' or 'reinforcement'. Behaviourism permitted associationism to be put to a fairly rigorous scientific test. However, experimental results from the study of putatively associative learning in a small number of basic experimental paradigms indicate that the process is considerably more complex than was originally thought. For example, the strengths of associations do not develop independently of one another. Whether or not the temporal pairing of two stimuli - say, the appearance of a diagonal red stripe on a round plastic button followed a few seconds later by the presentation of food to a pigeon - does or does not produce an association (in this case, between the stripe and the food) depends on the strengths of other associations that have developed prior to the current training or are developing during this training. If, for example, the average interval between food presentations is as high in the absence of the diagonal stripe as it is in its presence, the experimental chamber itself becomes strongly associated with food, and this association between the chamber and food blocks the formation of an association between the diagonal stripe and the food. The dependence of changes in one associative bond on the strengths of other associative bonds reflects the ability of the associative process to pick out the best and simplest predictors from among several competing stimuli that predict the occurrence of something important to the animal (hereafter called a 'reinforcer' because it strengthens the animal's reaction to the predicting stimulus).

A second complexity is that animals 'associate' two stimuli regardless of the temporal relation between them. 'Associate' is placed in quotes because it here means something much more vague like 'learns something about the temporal relation between'. If a stimulus reliably predicts the omission of a reinforcer, the animal learns an inhibitory association, that is, it learns that one stimulus predicts the omission of the other. If the two stimuli are made to occur truly randomly, so that knowledge of the time of occurrence of one provides no information about the time of occurrence of the other, then the animal learns that one does not predict the other. This is shown by a subsequent test in which the stimuli are temporally paired, so that now one stimulus does reliably predict the other. The exposure to the early truly random phase retards the animal's 'associating' the two stimuli in this second phase.

Note the difficulty of conceptualizing the learning in the truly random phase as the establishment of a conductive link (a true association) between the two stimuli. The one stimulus neither excites nor inhibits an expectation of the other - the only possibilities in a purely associative theory of learning - and yet the animal has learned something. Thus, it is difficult to conceptualize this learning in associative terms, because it is difficult to say what has become associated with what.

The discovery of the subtleties of the associative process in simple animal learning paradigms has led many modern theorists to adopt a more cognitive interpretation of the associative process. The process seems to depend on abstract relations between stimuli such as 'contingency' rather than on simple temporal pairing. This more cognitive view has less neurobiological transparency, and seems to require something like the resources of a computational theory of mind (see Mind, computational theories of).

3 Probability and learning

In the eighteenth and nineteenth centuries, statistics developed normative theories of inference unconnected with human psychology, but bounded by human computational limitations. A typical statistical problem concerned resolving recorded observations into a function of quantities satisfying a deterministic regularity and a quantity, representing the sum of a multitude of unknown quantities influencing the observed values, satisfying a probability distribution. After Legendre's development of least squares early in the nineteenth century, that method soon dominated practice in astronomy and geodesy. Laplace and Bayes advocated methods of learning involving forming new probabilities by conditioning old (or 'prior') probabilities on new evidence. George Boole attempted to develop more general probabilistic methods for inferring causes, but his proposals had little success.

Late in the nineteenth century Pierce introduced the idea of randomization in experiments, and Fisher's elaboration of that idea early in the twentieth century led directly to almost all of modern experimental design in the non-physical sciences, establishing a norm about how causes are to be learned in subjects from biology to economics (see Statistics; Statistics and social science). Roughly in the same period, the work of Galton, Pearson and Yule on regression, correlation and contingency tables led to the application of regression and association for causal inferences from non-experimental observations. Yule himself carefully investigated the limitations of such methods, which are still widely used but regarded as unreliable by experts. Beginning at the turn of the century, a number of psychologists developed the methods of factor analysis, which amounted to algorithms for generating theories of how unobserved features influenced observed quantities.

There are two approaches to probability theory, 'objective' (for example, 'frequentist') ones, which emphasize how the probability that something is *G*, given that it is *F*, is a function of the number of *F*s that have been *G* in the past, and 'subjectivist' ones, which emphasize the degree of a person's confidence in a hypothesis (see Probability, interpretations of). Introduced by Ramsey and De Finetti early in the twentieth century, the modern formulation of subjective probability treats probability as a measure of degree of belief, utility as a measure of desire, maximum expected utility as a decision principle, and conditional probability as a (normative) mechanism of learning. This 'Bayesian' perspective offered at least the framework of a general theory of inference and decision, but its practical influence was very limited both because of the dominance of frequentist ideas in statistics, and because the calculations required by Bayesian norms in even simple problems were beyond unaided human capacities. Kahneman, Tversky, Dawes and many others have shown regularly reproducible forms of human judgment that seem to violate Bayesian norms, but others have argued that such experiments fail to capture the range and frequency of decision-making tasks in which human competence evolved, and for that range of tasks human psychology satisfies Bayesian norms (see Rationality of belief). Others have offered speculations about how the nervous system may implement (unconsciously, of course) Bayesian computations (see Probability theory and epistemology; Rationality, practical).

Using either the calculus of probability or logical 'partial entailment' relations, or simply *modus ponens*, Keynes, Carnap, Reichenbach, Hempel, Popper and others proposed theories of 'confirmation' or 'corroboration' of hypotheses (see Confirmation theory; Inductive inference). These proposals concerned themselves largely with the a priori justification of hypotheses; no attempt was made to show that the confirmation relations they defined coincided with procedures for reliably discovering the truth, that is, for learning. These were regarded as issues exclusively for psychology. Concern with capturing reliable methods has come to dominate recent theories of learning, and 'reliabilist' approaches in epistemology generally (see Reliabilism).

4 Learning and computation

Using logical methods derived from Frege, Carnap and Russell sketched the 'construction' of concepts of properties, objects, and spatial and temporal relations from categories held to be more immediate: 'sense-data' in Russell's case, recollections of similarity between two 'elementary experiences' - Gestalt episodes - in Carnap's case (see Sense-data; Logical positivism). These theories of concept formation were not offered as mathematical psychology but as analyses (explications) of ordinary concepts (see Concepts §§3, 5-6; Conceptual analysis). Carnap's theory had the distinction of being algorithmic, and might arguably be considered the first attempt at an artificial intelligence programme (see Artificial intelligence).

The advent of the theory of computation and the digital computer prompted a number of related developments in

the middle of the twentieth century. Psychologists began exploring algorithmic procedures for learning. Under the guise of ‘concept learning’, Bruner and his colleagues, and later Hunt, developed effective versions of Francis Bacon’s methods. From instances of the predicates involved, these programs learned universal biconditionals with a single predicate on one side and any logical formula not containing that predicate on the other side. The psychologists gave some rather sophisticated thought to how the representation of propositions influences the computational complexity of their application in inference. The subject of artificial intelligence was born at the same time, and it immediately focused on how to make computers simulate learning. Although none of these algorithms was an accurate description of human learning, they were used to promote the proposition that various aspects of human learning may be algorithmic or computational.

Chomsky revolutionized linguistics by supposing that language speakers recognize grammatical sentences, and distinguish them from non-grammatical sentences by using an unconscious algorithm. He proposed that humans acquire the algorithm for their native language by applying a highly specific learning procedure specific to language and shared by all people. Chomsky claims that the procedure (‘Universal Grammar’) is not, itself, learned along ‘empiricist’ lines, but is innate along lines he associates with the early Rationalists. The idea naturally raised many questions of a kind that still trouble cognitive science and linguistics: how can we know whether there is a special learning facility for language? If there is such an algorithm, any human language must be of a kind the algorithm can learn from the evidence available to children (see Language, innateness of). How does that restrict the languages that are possible for humans?

The last question has been addressed in part by computational learning theory, a subject that has one of its roots in the philosophy of Hans Reichenbach. Reichenbach had argued that the aim of inductive inference is to judge limiting frequencies, and that the simple rule of guessing that limiting frequencies equal observed frequencies converges to the correct limit if a limit exists. His student, Hilary Putnam, combined Reichenbach’s long-run, reliabilist perspective with recursion theory to create one branch of the modern subject of computational learning theory. The framework for a discovery problem assumes that a set of alternative hypotheses are to be assessed, and any member of a set of (infinitely long) data streams is possible; each hypothesis is consistent with some data streams and inconsistent with other data streams. The investigator is idealized as a function from initial segments of data streams to hypotheses. The investigator succeeds on a data stream provided that the function representing the investigator has a false (for that data stream) hypothesis as its value on at most a finite number of initial segments of the data stream. The investigator solves the discovery problem provided it succeeds on every possible data stream allowed in the formulation of the problem.

The framework captures many reliabilist intuitions, and it has the further virtue of flexibility: success criteria can be altered; the relation between data streams and hypotheses can be altered; and constraints of many kinds can be imposed on the function representing the investigator. It does not represent inductive success as getting the correct answer in the infinite future, but rather as getting the correct answer after a finite amount of evidence is acquired, but without any fixed guarantee on how large ‘finite’ will be.

Putnam, and independently at about the same time, E. Mark Gold, characterized when a problem can be solved by an effective learner - that is, one whose learning function is a Turing machine (see Turing machines). Gold subsequently adapted the framework to model language learning, where a language is represented as a set of numbers that can be listed by a computer. For some collections of possible languages, there exist algorithms that can learn any language in the collection; for other collections, no such language is possible. On the Chomskian view, the collection of possible human languages must be of the first kind, a learnable class. So, by studying algorithms, something can be learned about the structure of human language. Computer scientists investigated both the language framework and a related one in which the data streams are graphs of recursive functions.

Kelly developed the framework into topological, measure-free alternatives to statistical analyses of reliable inference, with a whole class of counter examples to standard philosophical morals about methods of inquiry. For example, there are solvable (by computable learners) problems that cannot be solved by computable learners that output only hypotheses consistent with data received and background assumptions; other solvable (again, by computable learners) problems that cannot be solved by computable learners who change hypotheses only when they are contradicted by the evidence; and still others that cannot be solved by computable Bayesian learners. For learners that do not have to be computable, traditional confirmation strategies fail to solve discovery problems that

can be solved by other means. Kelly showed there is a universal strategy that succeeds whenever success is possible but is neither Reichenbach's nor Popper's. Virtually every methodological principle advanced by philosophers of science turns out to be sub-optimal or to entail some sacrifice of reliability.

Social aspects of learning have been undertaken in the context of computational learning theory, usually as studies of 'team learning' in which a number of parallel investigators process data and success requires that only one of them succeed. Recently, using very simplified reliability frameworks, Kitcher has provided an economic analysis of social gains in reliability when investigators compete and cooperate with the selfish aim of being the first to learn the truth about a scientific question.

We are still far from understanding how humans develop so that they distinguish relevant features of the world and know the causal relations among everyday circumstances. A theory about algorithms for learning causes has recently developed in philosophy and computer science, but psychologists have not yet compared it with human performance, and statistically sophisticated psychological models of human judgment of causality are only now appearing.

Lebensphilosophie

In its most general sense Lebensphilosophie *denotes a philosophy which asks after the meaning, value and purpose of life, turning away from purely theoretical knowledge towards the undistorted fullness of lived experience. In the second half of the nineteenth century and the early twentieth century the concept of 'life' assumed a central role in German philosophy.* Lebensphilosophie *typically opposes rigid abstractions with a philosophy based on feeling and intuition, and seeks to establish the priority of 'life' as an all-encompassing whole. The central claim underlying its various manifestations is that life can only be understood from within.*

The first recorded use of the term *Lebensphilosophie* is in a 1772 collection of essays by G.B. von Schirach, *Über die moralische Schönheit und Philosophie des Lebens (On moral beauty and the philosophy of life)*. In the late eighteenth and early nineteenth centuries the expression was employed to characterize a philosophy for practical life and was used synonymously with terms such as *Lebensweisheit* (wisdom of life) and *Lebenskunst* (the art of living) in order to provide general ethical and practical maxims for correct living.

While there are obvious points of continuity with this popular usage, the roots of the modern conception of *Lebensphilosophie* should, more generally, be traced back to the mid-eighteenth-century reaction against Enlightenment rationalism. The emphasis on feeling and immediacy, and the lived experience of truth in the work of figures such as Hamann and Herder, together with the search for a unifying principle prior to the abstractions of reason, leads to a prioritization of 'life' over 'mere understanding'. The *Sturm und Drang* mobilized a set of fundamental oppositions - between the living and the dead, the concrete and the abstract, the organic and the mechanical, the dynamic and the static - whose influence is carried through to modern *Lebensphilosophie* in the Idealism of Schelling and the early Hegel, as well as the Romantic attempt to establish the identity of philosophy and life, poetry and thought (see Romanticism, German).

However, the centrality of the concept of 'life' to German philosophy in the decades between 1870 and 1920 cannot be understood without reference to the work of Schopenhauer and Nietzsche. Schopenhauer's concept of the will as a single, unifying principle is both a precursor and model for subsequent attempts to grasp life as an all-encompassing metaphysical category: here the critique of rationalism first takes on the form of a metaphysics of the irrational. In contrast, Nietzsche's importance resides in his attempt to explicate truth in terms of its function for life, and his insistence on the dynamic, historical and conflictual character of human claims to knowledge. A third and later figure of comparable importance is the French philosopher Henri Bergson, whose conception of time as lived experience exercised an enormous influence on German philosophy in the late nineteenth and early twentieth centuries. Bergson's ideas were taken up as part of the vitalist opposition to scientific materialism and the attempt to show that life cannot adequately be explained in mechanical and physical terms: biology rather than physics provides the central categories for understanding life in its own terms (see Vitalism).

Lebensphilosophie must also be seen as part of a broader cultural movement which extended beyond the confines of philosophy. This movement is marked, on the one hand, by a striving to overcome, through a vitalistic affirmation of the fullness of life, the limits placed on the isolated individual, and on the other hand by a mood of pessimism and decadence which received its most powerful expression in the arts. In the work of figures as diverse as Georg Simmel, Ludwig Klages and Oswald Spengler, the concept of life is taken up as a critical category by means of which the conflicts and contradictions of modern society could be identified and diagnosed.

There are two principal reasons for the relative obscurity into which *Lebensphilosophie* has fallen today, despite the dominance which it exercised prior to and immediately after the First World War. The first is the extent to which some of its principal insights were taken up in a methodologically more rigorous and productive way in Husserlian phenomenology and Heidegger's 'philosophy of existence' (see Heidegger, M.). The second is the extent to which the irrationalism and cultural criticism of *Lebensphilosophie* fed into the doctrines of National Socialism. Perhaps the most enduring achievement of *Lebensphilosophie* is to be found in the work of Wilhelm Dilthey. His emphasis on the concrete fullness of lived experience and the diversity of the manifestations of social and cultural life prior to the abstractions of reason results in a new attempt to ground philosophically the human sciences and the important methodological distinction between *Erklärung* (explanation) and *Verstehen* (understanding) (see Explanation in history and social science).

Lefebvre, Henri (1901-91)

Henri Lefebvre was a Marxist and existential philosopher, a sociologist and a theorist of the state. His humanistic neo-Marxism has been influential throughout Europe. In the English-speaking world he is best known for his analyses of 'everyday life', his work in the sociology of urban and rural life, and his theory of social space. Lefebvre was one of the most prominent early critics of structuralism, and is considered by some to be the first post-structuralist. He was a relentless critic of academic philosophy's metaphysical tendencies.

During the 1920s, Lefebvre was associated with the surrealist movement in Paris, and his work from this period has been described as proto-existentialist. In 1929, however, he joined the Parti Communiste Français (PCF) and by the 1940s had become the PCF's leading intellectual spokesperson and a Marxist critic of Sartrean existentialism (see Sartre, J.-P.; Marxism, Western). With Norbert Guterman, Lefebvre was the first to translate the works of the young Karl Marx into French, and his *Le Matérialisme dialectique* (*Dialectical Materialism*) (1939) earned him the title 'Father of the Dialectic' in France. He was also the first interwar writer to attempt an anti-fascist reading of Nietzsche, and one of the few to publish rigorous critiques of nationalism and National Socialism.

Lefebvre's main philosophical work, *Logique Formelle, Logique Dialectique* (Formal logical, dialectical logic) (1947a), provides a critique of formal logic and categorical reasoning. In 1957 he was excluded from the PCF for his attacks on Stalinism and his humanist unorthodoxy, and was subsequently reconciled with Sartre. In the 1960s he inspired figures in the French avant garde, including his teaching assistant Jean Baudrillard and members of the Situationniste Internationale, many of whom were his students, including Michele Bernstein, Guy Debord and Daniel Cohn-Bendt, the student leader of the May 1968 demonstrations in Paris. The failure of those demonstrations to lead to substantial changes in the French way of life was seen, however, as an indictment of Lefebvre's method of revolution-through-festival, derived from the surrealists; in subsequent years his humanist Marxism came under direct attack from Althusser's 'Scientific Marxism' (see Althusser, L.P.).

Lefebvre's influential interpretation of Marxism was similar in tone to that of the young Georg Lukács, emphasizing alienation as the central concept of Marx's thought. Alienation in the economic sphere was explored using the tools of historical dialectical materialism, a methodology on which Lefebvre placed great store; but he also argued that Marxism would remain incomplete so long as it was restricted to the economic sphere rather than incorporating all aspects of life. He presented three-part dialectics in order to undermine the tendency to simplistic dualisms apparent in much Marxist thought. Lefebvre's 'retro-jective' method, by which he attempted to operationalize historical materialism for research purposes, provided the basis for Sartre's regressive-progressive method.

In his *Critique de la vie quotidienne* (*Critique of Everyday Life*) (1947b) Lefebvre critically analyses the banality of life in the modern world in terms of the 'mystification' of its alienated, boring quality. His theory is a reinterpretion of Lukács' and Heidegger's notion of 'everydayness' or banality (*Alltäglichkeit*) in the more sociological terms of alienation and everyday social routines. In this, he is a precursor of the work of Bourdieu on habitual routines ('habitus'). A 'romantic revolutionary', Lefebvre sought a 'revolution in everyday life' in which spontaneous, ludic expression would be liberated from the restrictions of authoritarian rationality and alienated routine. He was one of the first authors to theorize the malaise of everyday modern life in terms of the 'globalization' of production.

Lefebvre was a founder of rural sociology and of applied sociology in France, where he established the first Institute of Sociology at Strasbourg. In the 1960s and 1970s, as a professor at Nanterre, he concentrated on urban problems, presenting his theory in the 1974 work *La production de l'espace* (*The Production of Space*). He argued that notions of spatiality, the interaction of bodily action and the constructed environment, and theories of geography are all aspects of a social space created by people, not something which occurs naturally. This 'space' is a dialectical product of social activity which reacts back on social action to channel it in a continuous dialectic of ongoing 'spatialization'. In the English-speaking world, where Lefebvre's Marxist and existentialist theories are less well-known, his most enduring influence has been in the fields of geography, urban planning and cultural theory.

Lefebvre served as a conduit for ideas from generation to generation, including surrealists (1920s), Marxists (1930s), existentialists (late 1940s) and situationists (early 1960s), to American neo-Marxists and analysts of late-twentieth-century postmodernity, such as Fredric Jameson and David Harvey. His key ideas of autonomous self-organization and spontaneity influenced the German Green Party and East German artists' movements, and British punk-anarchist subcultures in the 1980s.

Legal concepts

Concept-formation is an important component of law-formation. Well-developed legal orders are profoundly conceptual in nature. Throughout Western legal history, legislators have aimed at basing their law-making on concepts of a general scope (such as 'property', 'possession', 'usufruct', 'criminal intent' and many others) - and even more so legal scholars in their reconstruction and development of law. Legal thinking makes use of concepts with many different functions and varying logical status. A distinction can be made between concepts that are an integral part of law themselves (here called L-concepts) and concepts that belong to the professional vocabulary of lawyers and jurists in their handling of the law (J-concepts). Among the L-concepts there are on the one hand concepts whose meaning is totally determined by the rules of one single legal system and on the other hand concepts that pertain to two or more legal systems. The latter concepts have a comparative function.

J-concepts provide lawyers with a language enabling them to give an intellectual structure to the legal material, to characterize and discuss the professional-juridical handling of law and the methods used for performing that task, to specify the functions of law and to formulate the underlying values of (the handling of) the legal system.

There was a tendency in earlier legal philosophy to hypostasize legal concepts, for example, the concept of 'right' in classical natural-law doctrine: that is, to postulate real entities to which our concepts/terms refer. The legal philosophy of the twentieth century has to a large extent been a reaction against this tendency. This reaction has taken three different directions: (1) to reduce the abstract legal concepts to factual phenomena such as certain human behaviour or socio-psychological factors (mainly within US and Scandinavian realism); (2) to assign to legal concepts a normative ontological status, placing them in a world of norms, distinct from the world of facts; and (3) to analyse legal concepts in a contextual setting, that is, to find out how they function in actual legal discourse.

1 Legal concept-formation: L-concepts and J-concepts

Legal orders have, historically, emerged from a need to restrain unhampered human violence. In more developed legal orders, rational argumentation has to a large extent superseded violence as a means of solving social problems. Western legal orders, based on or at least influenced by Roman law and the dogmatic study of it since the end of the eleventh century, have a strong intellectual stamp: disputes shall be solved according to general principles and vital social relationships defined with accuracy by precise legal concepts. 'Normative order…is…a hard won production of organizing intelligence' (MacCormick (1990: 557). Just as theory-formation and concept-formation in science are 'so closely interrelated as to constitute virtually two different aspects of the same procedure' (Hempel 1952: 1), there is a similarly close connection that verges on coalescence between law-formation and concept-formation. Western science and Western law equally rest on a common base - rationalism - which has its roots in the world of ideas of ancient Greece and Rome. Well-developed legal orders are profoundly conceptual in character.

Legal thinking, in all branches and on all levels, makes use of concepts with very different functions and of varying logical status. Let us, roughly, compare the conceptual world of, for example, a zoologist and that of a lawyer. The zoologist, like all other professionals, needs in his work a professional (technical) language. This language refers in different respects to the subject matter of zoology - foxes, halibuts, wings, cells - which are mainly entities of a physical nature (things). In contrast to the zoologist's vocabulary, the lawyer's vocabulary refers to the subject matter of the law, which is a language (a product of human culture) too, with an abundance of terms signifying different concepts. Thus, in the legal sphere of life we have to allow for two, in principle distinct, languages: the legal one (in a proper sense) - the object language - and the juridical one - the meta-language. We refer to the concepts of the first category (concepts of law) as legal concepts proper (L-concepts) and to the concepts of the latter category (concepts about law) as juridical concepts (J-concepts). L-concepts have a law-stating function, while J-concepts have a juridical-operative function.

Let us start with the L-concepts. Within this category we can distinguish between L-concepts pertaining *uniquely* to one single legal system, for example, French law (UL-concepts, where 'U' indicates this kind of 'uniqueness'), and L-concepts pertaining to two or more legal systems, comparative L-concepts (CL-concepts). (A legal system is here regarded as a set of legal norms, or rules.)

A UL-concept is an L-concept that is wholly dependent, with regard to its meaning, on the content of a given legal system at a given point of time (for example, the law in force in France on 1 January 1994). If a given concept, for example, ‘ownership’, is a UL-concept, then the meaning of ‘ownership’ is completely determined by the prerequisites (descriptions of legal, or operative, facts) and the legal consequences which, in a given legal system at a given point of time, decide how ownership arises and expires, as well as what the legal effects (the legal significance) of ownership are. From this it follows, for example, that the Swedish concept of ownership differs somewhat from the Norwegian one, and also that it is changed as soon as the legal rules (‘the ownership rules’) are changed with respect to the above-named descriptions.

A CL-concept is an L-concept whose meaning is dependent on the content of two or more legal systems. Suppose that a jurist is interested in the concept ‘marriage’, not with respect to some single legal system but to all, or some family of, legal systems. This amounts to finding the ‘lowest common denominators’ of all rules concerning marriage - the gist, as it were, of the phenomenon of marriage. This is, in fact, not a concept of any single legal system and hence, it might be argued, not a concept of law but a concept about law. But it is, no doubt, a concept of law in the respect that it is totally dependent on the content of legal systems - it is not a purely sociological concept. For the formation of CL-concepts the logical technique of ideal-type definitions is appropriate. CL-concepts might be of both scientific (within the field of comparative legal science) and legislative value (for example, in international legislative work of the kind that aims to harmonize different national legal systems with each other or to work out international rules in some particular sphere). As we have seen, one and the same term, for example, ‘marriage’, might signify both a UL-concept and a CL-concept.

2 UL-concepts: further distinctions

Within the category of UL-concepts some further distinctions can be made.

Antecedent and consequent UL-concepts

Take the legal rules

(r_1) If *a* owns *o*, then *a* is allowed to use (sell, pawn,…) *o*.

and

(r_2) If *a* has bought or inherited or received as a gift or… (and not sold, or…) *o*, then *a* owns *o*.

In r_1 ‘ownership’ refers to legal (or operative) facts; the phrase ‘if *a* owns *o*’ is shorthand for ‘if *a* has bought or inherited or received as a gift or… (and not sold or given away or destroyed or…)’; ‘ownership’ is a prerequisite expressed in the antecedent of r_1.

In r_2 ‘*a* owns *o*’ is shorthand for ‘*a* is allowed to use and sale and pawn and lease and…*o*’; ‘ownership’ here refers to the legal effects (or legal significance) expressed in the consequent of r_2.

In the Scandinavian discussion on rights in the 1940s and 1950s (initiated by Per Olof Ekelöf; see Wedberg 1951) the function of right-concepts in legal discourse (legislative, dogmatic and so on) was regarded as a shorthand-function. If we combine the antecedent of r_2 and the consequent of r_1 we get

(r_3) If *a* has bought or inherited or received as a gift or… (and not sold, or…) *o*, then *a* is allowed to use (sale, pawn,…) *o*.

where, apparently, the concept ‘ownership’ is not to be found - an observation which induced Alf Ross to the idea that right-concepts are semantically meaningless vehicles of deduction (Ross 1957).

Genuine and non-genuine UL-concepts

A UL-concept has a genuine or non-genuine function depending on whether it appears in genuine or non-genuine legal statements in the sense indicated by Ingemar Hedenius (1941). Let us explain this - now internationally accepted - distinction with the help of an example:

(r_4) Anyone who travels by car in Sweden must drive on the right-hand side of the road.

This statement can be understood in two different ways. If r_4 appears in an official statute it is natural to understand r_4 as a normative statement, a decree, which the legislator has issued with the intention of directing a certain kind of human behaviour. Understood in this way r_4 is lacking in truth-value; it is neither true nor false. Statements with this function are genuine legal statements. But suppose that a Swede visits England and is asked by an English person what the rules of the road are in Sweden, and that in reply they utter the (somewhat magisterial) statement r_4. When they make this reply it is not their intention - at least not in the first place - to steer the questioner's behaviour; their intention is merely to inform the questioner of the content of valid Swedish law in this respect. And when r_4 has this function it is a non-genuine legal statement, and has as such truth-value; it is either true or false. Statements of legal dogmatics are usually of this kind. It is to be noted that r_4 has the same linguistic formulation irrespective of whether it is used in the genuine way or the non-genuine way, and that genuine and non-genuine legal statements are often formulated alike. But the non-genuine legal statement always contains, logically speaking, an explicit or understood clause 'according to valid law in S at t', where S is some society and t is a point of time. Thus, in its non-genuine function r_4 is equivalent - so long as Swedish law is intended - to the statement

(r_5) Anyone who travels by car in Sweden must drive on the right-hand side of the road according to (now) valid Swedish law.

Official and dogmatic UL-concepts

Official UL-concepts are found in statutes, preparatory materials, judgments and other official texts. Dogmatic UL-concepts are found in legal-dogmatic works (for example, 'causality', 'proximate cause', 'right *in rem*'). Dogmatic concepts can, but need not, have equivalents among the official concepts. Legal dogmatists can quite well create their own concepts when they consider that the official battery of concepts is insufficient, and this happens now and then. Such concepts can later be incorporated in the law. Historically speaking there are also a number of concepts which, as products of academic law, have found their way into municipal law or are implicitly contained within it. An official concept and a dogmatic one need not have the same meaning, even if they are expressed by the same term (for example, 'possession' in Swedish statutory language is not equivalent to 'possession' as it is used in Swedish doctrinal literature).

3 J-concepts

Turning to the J-concepts, the technical tools used in the legal-professional handling of legal orders (that is, of L-concepts), we may list some important functions of juridical language and distinguish between different kinds of J-concepts on the basis of those functions (the list is by no means exhaustive). We need:

1 a set of concepts helping us to structure the law in a logical and functional respect (morphological concepts);
2 a set of concepts helping us to describe in a precise manner the professional-juridical handling of the law (praxeological concepts);
3 a set of concepts helping us to speak clearly and articulately about the relations between the law and the social reality in which the law 'operates' and which it is designed to influence - in short, about the functions of law (teleological concepts);
4 a set of concepts helping us to describe in a precise manner the programmes (methods, principles, techniques) for the juridical handling of law, be it in legislation, administration of law, legal dogmatics or otherwise (methodological concepts);
5 a set of concepts helping us to articulate our ideas about the values pertaining to the juridical handling of law (ideological concepts).

As for morphological concepts, we can differentiate between two levels: micro-morphological and macro-morphological. At the former level it is the component parts of individual (types of) legal rules that are studied. Here we meet concepts such as 'prerequisite', 'legal fact', 'legal consequence', the various concepts for (Hohfeldian) legal positions (see Hohfeld, W.N.), the various normative modalities 'shall', 'may', 'must not'

(expressing obligation, permission, prohibition) and so on. At the macro-morphological level we study the component parts of legal systems, that is, different types of legal rules and different kinds of relations between such rules. As an example of such a classification can be mentioned Hart's distinction 1961) between primary rules and secondary rules (rules of recognition, rules of change and rules of adjudication) (see Hart, H.L.A.). As examples of relations between rules can be mentioned the concepts (*r* and *r′* are legal rules) '*r′* is analogous to *r*', '*r′* is in an e-contrario relation to *r*', '*r′* is an extensive interpretation of *r*' and so on.

As examples of praxeological concepts can be mentioned 'complying with the law', 'breaking the law', 'administration of law', 'application of law', 'interpretation', 'evaluation of evidence', 'pleading', 'statutory drafting' and so on - all concepts concerning different kinds of legal activities.

Teleological concepts (concepts about the functions of law) are, for example, those introduced by Raz (1979) - namely, 'primary', 'secondary' and 'indirect functions' - and also concepts describing the relationship between a legal rule, *r*, and some social aim or purpose, *p*, for example, '*r* is expedient with respect to *p*' or '*r* is effective with respect to *p*'.

The flora of methodological terms is rich and varies from country to country. The underlying concepts, however, are very much the same. Some examples are: 'objective', 'subjective', 'historical', 'intentional', 'linguistic', 'logical-grammatical', 'systematic', 'teleological' and 'pragmatical interpretation', 'reasoning by example', 'reasoning by analogy'. To the methodological arsenal of concepts also belong the concepts dealing with the factual basis of legal argumentation - the legal sources - such as 'statute', 'act', 'precedent', 'case law', 'custom', 'preparatory materials', and the concept 'legal source' itself.

Among the ideological concepts we find concepts such as 'legal certainty' (or 'predictability'), 'legality', 'equality before the law', 'the rule of law' and '*Rechtsstaat*' ('law-state').

4 Substantialism and its opponents

In the classical natural-law doctrine of the seventeenth and eighteenth centuries there is a tendency towards substantialism, that is, to Platonic hypostasizing of legal concepts (Hobbes is an exception, but he was after all not a full-fledged natural law philosopher anyway). During the last two centuries the development of sciences and logic has contributed to a sharpened awareness among legal philosophers as to ontological matters. The reaction against substantialism has taken three, in principle different, directions.

One is reductionism. This is an idea of venerable age. It is found as early as the time of the Presocratics, in their efforts to bring the apparent variety of entities back to one single substance. Its programme is clearly stated by Ockham (*non est ponenda pluralitas sine necessitate*; a multiplicity shall not be assumed unless it is necessary). In the legal philosophy of the first half of the twentieth century reductionistic tendencies are strong, especially within the US and Scandinavian realist movements. Here the reduction consists in reducing abstract ('fictional') legal entities to a certain kind of human behaviour or to socio-psychological pressures and reactions. (We assume that abstract concepts such as 'legal order' have the same ontological status as the abstract entities to which these concepts refer, for example, legal orders (see Legal realism).)

Another one is separatism. This consists in locating legal concepts in a separate ontological realm of their own. Kelsen's *Pure Theory of Law* is an endeavour to separate normative entities (which at least must include the L-concepts) from factual entities by differentiating the world of Is (*Sein*) from the world of Ought (*Sollen*) (see Kelsen, H.).

A third reaction against substantialism is functionalism. Instead of asking about some legal concept, *c*, 'What does *c* refer to in reality?', legal scholars with a functional approach formulate the analytical question like this: 'How does *c* function in legal thinking?' Hohfeld belongs to the functionalist jurists, his classic work on jural relations is indeed entitled *Fundamental Legal Conceptions as Applied in Judicial Reasoning*. Functionalism was also the explicit starting point for the fruitful discussion on rights that took place in Scandinavia during the 1940s and 1950s (Wedberg 1951). Hart's idea (based on Bentham; Hart 1954) that legal concepts shall be defined in a contextual setting (by contextual definitions) is in the same vein.

Apart from ontological differences concerning legal concepts, we can discern different attitudes as to their

importance in legal life, oscillating between extreme absolutism and extreme relativism. Absolutism is here taken to mean a tendency to regard legal concepts as perpetual (static) and also precise with regard to their meaning, and relativism as the opposite of this. The *Begriffsjurisprudenz* (conceptual jurisprudence), flourishing in Germany during the second half of the nineteenth century, is characterized by a high degree of absolutism: when confronted with some legal problem, for example, whether some clause in a contract is about an easement or a usufruct, the task of the lawyer was to ascertain whether the right in question fell under the concept ‘easement’ or that of ‘usufruct’, and when this was done the problem was solved, since the legal effects of, for example, easement were fixed beforehand and implicit in the concept itself. This kind of legal technique is, in fact, to a certain degree indispensable in any well-developed legal order, but what gave *Begriffsjurisprudenz* its bad reputation was that it grossly disregarded the social consequences of the legal decisions and overestimated the precision of the legal concepts.

Legal discourse

'Legal discourse' signifies a strong interplay between law and language, linking together law as like language and law as itself language. However, unlike other linguistically modelled accounts, this approach involves a strong opposition to formalisms and their mirror-image realisms. Language as used cannot be 'deduced' from any pregiven matrix or set of propositions but must be studied in terms of its own modalities. The theory of law-as-discourse takes inspiration from the study of legal rhetoric and from socio-legal analyses of the courtroom, but was developed in its own right in the post-structuralist turn in linguistics. Law-as-discourse requires an understanding of the operation of legal talk in different registers, and gestures towards an intertwining of the social, the legal and the linguistic by focusing on the speaker-hearer situation, locution and action.

1 Law as rhetoric

While the currency of the term 'discourse' derives from post-structuralist developments in linguistics, this type of analysis was inaugurated in law by two important precursors, the New Rhetoric movement and socio-legal courtroom studies. Both, like post-structuralism, sought to break with logicist-formalist models of language and parallel models of law as a code or system of ideally transparent propositions of universal import held together by a formalizable syntax. This rethinking, in turn, posed the problem of how to reconceptualize 'the social' as both impossible to differentiate from 'the legal' yet as constitutively law's 'outside'.

The New Rhetoric movement, led by Chaim Perelman and Lucy Olbrechts-Tyteca beginning in the mid-1940s, sought to examine the process of argumentation as a way of using language, with its own prescriptions and proprieties to be understood through a return to Aristotle and the Roman jurists, discursive techniques employed to move an audience to a decision to act. But this return required the dethronement of demonstrative reasoning. 'Any theory of argumentation must break with the notion of reason and reasoning which comes from Descartes and has left its stamp on western philosophy for 300 years' (Perelman (1963: 134). For Descartes, the very existence of dispute was the sign of error, since truth was marked by transparency and intersubjective agreement. In this tradition, rhetoric had thus languished, cast at worst as a mode of duplicity, sophism and deliberate audience-manipulation involving pseudo-logic and base, populist, appeals to the emotions; or at best a source of literary stylistic flourish.

Perelman had himself begun in the logical positivist tradition, arguing that justice was an ultimately meaningless concept. Although formalizable as 'treat like persons alike', the values of what would count as like persons or as like treatment were always contested and hence arbitrary and socially contingent. Yet where did this leave law, at all levels functioning through competing arguments, in the two-party structure of the appeal court as much as the courtroom?

More radically, justice turned out to be the rule rather than the exception. *All* formalizations suffered the same fatal flaw. 'The insufficiency of the strictly formalist attitude becomes clear as soon as the question of interpreting a logistic system arises. But without attribution of meaning, axioms are not assertions' (Perelman 1963: 148) but merely arbitrary computations. Frege's conceptual Platonism, Tarski's factual correspondences, and the rise of conventionalism all testified to formalism's need for an extra-systemic semantic supplement - which, thus beyond control of the system, undermines its fundamental claim to autonomy and closure. Meaning/value was in turn (as with justice) always contestable. Thus, as it would be put subsequently, if law operates around a core of settled meaning, 'settled' does not mean pregiven and linguistically fixed but merely not currently in dispute (Jackson 1985: 156).

Shifting direction, Perelman came to see that disputation was a more orderly process that grew out of the engagement between speakers and hearers rooted in a common frame of reference, beginning with a prescribed understanding of their correlative roles and associated forms of diction (thus, teacher-pupil, fellow citizens). Assuming that all parties have a common concern to do justice, but that the audience's conceptions of this will begin in the familiar, the effective orator will tailor argument to the local audience. For every proverb there is a counter-proverb. The speakers thus lodge their recommended courses of action within contrary realms of meaning - different construals of what it is right to do - available via one or another 'locus of the preferable'. In a key example, Perelman 1979) contrasts the loci of quantity and quality respectively as asserting the durable, the useful,

the accessible, constant, symmetrically ordered, that which is useful to the greater number, the eternal and the abstract, being and form, as against the unique, the original and the difficult, the natural, the irreplaceability of the moment and the individual, the instant as the figure of totality, the poetic mode that recognizes the uniqueness of the other and the particularities of love and obligation. There are also prescriptions for the temporal ordering of argument.

Rhetoric is sometimes glossed as describing 'who can make arguments and where (and in what terms)', as does Perelman (1979) when commenting that rhetoric has always been a matter of political regulation. But here a great danger lies. In emphasizing the (indubitably) political nature of the designation of who can speak and hear, the social nature of discourse tends to be cast as an externality. Correspondingly, to speak of 'what' can be said loses the fact that the 'what' of speaking consists in the 'how'.

This example also holds together a fundamental tension in Perelman's work. The drive on the side of the locus of quantity takes him to develop a normative account of argumentation as justification in relation to a universal audience and a democratic politics, in keeping with rhetoric's birth in the agora of open political debate and a broad conception of logic that encompasses probabilistic reasoning. This is what links his work to rationalist theories of legal discourse (see Legal reasoning and interpretation §3; Habermas, J. §4).

On the other hand, Perelman also recognizes rhetoric as having a certain generic affiliation with the locus of quality, being ever about materialities rather than abstractions, audiences being always local. Rhetoric and common law reasoning share the need to cast the new in relation to tradition and customary practice and their 'crabwise' form of connection by way of analogy. Hence too law's generic conservatism and endorsement of any prevailing 'sense of normality, or likelihood' (Goodrich (1987: 181). More hopefully, others, such as Boyd White 1985), would emphasize the heterogeneity of community with its contesting hierarchies of value: what is common as merely the starting point of cultural transformation of meaning.

To follow the materialities of rhetoric is perhaps most promising. Goodrich's *Languages of Law* (1990) thus associates together rhetoric's use of place (topos/locus) and sequence with the bodily, the way that memory techniques are situated in imageries of dwelling places, or streets, the idea of patterns linking cases, with the idea of habit as images or emblems of how to live. Similarly, the figurative dimensions of texts may speak a different and more revealing story than their propositional mode, as Douzinas, following de Man, has shown most effectively by looking at Dworkin's Hercules metaphor (Douzinas *et al*. (1991). The dimension of time and sequence is equally important: moving an audience means moving them through a series of positions and differential engagements or 'identifications' in which each stage is dependent upon the former. Legal discourse becomes a kind of memory garden. Rhetoric, as Perelman constantly emphasized, is about effecting a *change* in the hearer, by contrast to the atemporal quality of demonstrative reasoning. In this mode Bernard Jackson 1988) has argued that the 'real time' of the trial process cannot be reduced to its retrospective view, in which the end is summed in the eternal non-time of legal or logical justification.

2 Courtroom studies

Socio-legal studies of the courtroom are the natural locus of legal rhetoric as forensic argumentation and, in turn, are ever in danger of lapsing into seeing rhetoric as low persuasion. However, in contributing to the study of law as discourse, they deal with two key issues: differential audience address and the relation between legal and non-legal discourse.

Law's address is multiple. Perelman considered this divided locution in terms glossed by Hart (in the introduction to Perelman (1963): the 'rhythms' of the 'natural' 'common' language are quite different from the 'technical language' common to members of a discipline or profession, language that is the 'private preserve of initiates' 1963: 156). As Pat Carlen (1976) insisted, this split address raises serious problems of legitimization, law's continuing need, internally and publicly, to be seen to be acting according to principles of justice and fairness. This is constantly under strain because of law's existence as both formal-constitutive abstract rules and situational rules determining the use of law in practice, which she links to the socio-linguistic categorization of elaborated and restricted codes. The elaborated code being characterized in terms of flexibility, the availability of many alternative expressions, abstraction, context-independence, enabling talk between strangers, and characterizes law's universalistic diction, its general language of justification. But, in its situational usage, law operates

according to a restricted code, highly concrete and local, a kind of argot, highly context-dependent, indexical, non-transportable and poor in substitute expressions, a use of language typical of closed communities with fixed structures - in this case primarily the closed community of lawyers. The lay 'audience' - which includes parties to the proceedings - thus suffers a double cognitive dissonance. (Carlen then goes on to describe the 'remedial routines' by which any resulting protests are discounted.)

Bennett and Feldman's focus (1981) is closer to the concern with argumentation, now inflected in terms of the question how juries make sense of legal arguments in trial courts in reaching their verdict. They find the bridging feature to be not the classical tropes of rhetoric but, rather, the literary mode of narrative. The story-form allows legal categories to be filled in with everyday meanings. Argumentation here means, precisely, the ability of prosecution or defence to produce a properly constructed story, potentially outweighing a more 'scientific' assessment of the evidence (as well as importing social prejudice). While providing an important counter to more abstract and philosophical understandings of narrative as coherence (MacCormick (1978), they barely glimpse the significance of narration - the way of telling the story: that very I-you relationship central to rhetoric - and law as discourse.

3 Legal discourse

The official theorization of law as discourse draws directly on linguistics, in which the term 'discourse' exists as a paradox. It begins as a stated definition: any stretch of language longer than a minimal unit of meaning (conventionally, a sentence). But filling out that definition immediately puts in question the ability of any 'minimal' unit to function autonomously, to have meaning in isolation from the discursive context in which it is bedded. Any smaller unit - a sign - does not have meaning, yet a sentence is already a miniature 'environment'. This is a more sophisticated statement of Perelman's critique of formalism as always in need of a semantic supplement.

Linguistic formalism is here construed broadly to encompass both Anglophone reference-based logical positivism and Francophone code-based structuralisms. Formalism's failure is that it cannot account for the meaning or function of any particular instance of speaking, carving it up, rather, between a 'logical deduction' from the system - the actualization of one of a matrix of given possibilities - and the residue, cast as unanalysable social and psychological contingency that can be registered only diachronically when such usage builds up sufficient critical weight to feed back into redefining the system itself. Discourse theory begins, rather, from speaking, the speaker-hearer relationship and how that is linked to its discursive context. The meaning of terms cannot be taken as transparent but is determined by its existence in different discursive formations and use in different registers.

The most ambitious attempt to theorize law in these terms is found in Peter Goodrich 1987). Drawing together a barrage of discourse theorists, but centrally Pêcheux (1982), the book offers a double attack on conventional jurisprudence (see Legal hermeneutics). On the one hand, most of modern jurisprudence is cast into the realm of formalism with its symptomatic failings. On the other hand, those things which jurisprudence takes to be law's essential features - its unity and coherence, its singular monolithic voice of authority, can themselves be shown to be effects produced by identifiable discursive techniques and social violences. (There is a perhaps surprisingly *marxisant* tone reminiscent of exposés of the tricks of ideology.)

Law's self-representation is disposed under the category of 'intra-discourse', designated the surface level, that describes the actual discursive techniques of law's utterances. The image of law as a coherent, auto-authorizing body is thus effected by law's continuing construction of its own history, as maintained by closure mechanisms of exclusion and discursive techniques of linkage, co-reference and internal continuity yielding the sense of a location in a continuous time: all context-dependent mechanisms that found law's claims to be universal and context-independent. Unlike Perelman, who strongly contrasted law as rhetoric (as a continuous address to an audience) to dialectic and other forms of dialogue, Goodrich claims that law pretends to be a dialogue but is really a monologue.

The level of institutionalization is, similarly, presented in terms of what is excluded from visibility and, further, posited very strongly here as a social externality that determines membership conditions of law's internal point of view. Less crudely, these cultural acquisitions evoke something of Bourdieu's account of 'knowing how' as a set of dispositions or postures, or Duncan Kennedy's 'training for hierarchy' that might locate the lawyer's

'belonging' in a more properly inarticulate and generally cultural form.

Third, and finally, there is the level of inter-discourse, law's relation to other discourses. Law's univocal mode suppresses the multi-vocal heteroglossalia of the social and law's self-referentiality means that it is an impoverished language cut off from denotation. 'Far from being expressly bound by any extra-linguistic content or denotative meaning, law's terms are connotative and symbolic: they lend themselves to an obfuscating, rhetorical or symbolic usage, to figurative or analogical manipulations within which their actual menage or referent is obscure' (Goodrich 1978: 179). This is a rather puzzlingly traditional characterization.

Although this is a highly reduced account of the book, in many ways, this is not the best of Goodrich's texts to study in order to understand what it means to look at law as discourse. What he provides elsewhere is a rich and dense series of accounts of law as compacting together many different specific genres of writing, traditions of interpretation and inscriptions of memory. It is in these works, rather than theorization, that the fruitfulness of approaching law as discourse can be seen.

Legal evidence and inference

In the field of law there is a rich legacy of scholarship and experience regarding the properties, uses and discovery of evidence in inferential reasoning tasks. Over the centuries our courts have been concerned about characteristics of evidence that seem necessary in order to draw valid and persuasive conclusions from it. Thus, they have been led to consider such matters as the relevance of evidence, the credibility of the sources from which it comes, and the probative or inferential force of evidence. Court trials usually involve inferences about events in the past. The past can never be completely recovered. In addition, evidence about past events is frequently inconclusive, conflicting or contradictory, and often vague or ambiguous. The result is that inferences about past events are necessarily probabilistic in nature. Our courts have also been concerned about whether the interests of fairness require that, on occasion, evidence might be inadmissible, even though relevant and credible. Evidential and inferential issues such as the ones just mentioned are also of concern to philosophers and persons in other disciplines. This entry concerns several evidential issues of particular interest in legal contexts.

1 Proof and admissibility

Evidence in legal contexts has some distinctive features. Two issues are central in modern scholarship on evidence and inference in legal contexts. The first concerns study of the properties and uses of evidence in the process of judicial proof. To be persuasive in the process of proof, evidence must have certain ‘credentials’ established by defensible arguments (see §2 below). The second issue concerns study of rules regarding the admissibility of evidence. Not all legal systems have such rules. In ones that do, evidence with justified proof-related credentials is still not necessarily admissible at trial. Concern about the proof credentials and admissibility of evidence has not always been as great as it is today. This concern intensified very slowly as adversarial processes for settling disputes and the concept of jury trials came into existence.

In England in the eleventh and twelfth centuries, persons accused of crown or criminal offences had the burden of proving their innocence. This burden was discharged in three stages: judgment, trial, sentence. At the judgment stage the accused was obliged to select one of three methods of ‘proof’: by the swearing of oaths by witnesses, by ordeals of various kinds, or by combat. The trial thus simply consisted of the implementation of one of these methods. The trial outcome depended not on any evidence but on the judgment of God. It was then believed that, if the accused was truly innocent, God would strike down anyone who gave a false oath against the accused, would heal any injury inflicted on the accused during an ordeal, and would side with the accused in a trial by battle. Sentence was then delivered in accordance with God’s verdict. With the decline of proof methods based upon oaths, ordeals and combat, jury trials gradually came into existence. But in their earliest forms these juries consisted of witnesses against the accused as well as other persons having vested interests in the case. They were not seen as objective triers of facts.

Interest in evidence emerged as the jury came to be identified not as witnesses but as a body of persons who deliberate impartially upon evidence given by external witnesses for both sides of a dispute. Thus, advocates came to be concerned about the evidential merits of their own cases and how effectively they could counter the evidence and arguments given by an opponent. A landmark case occurred in 1670 regarding the role of jurors in the process of proof. Prior to this time, jurors could be attainted for giving verdicts contrary to what the court regarded as manifest evidence. In the case of Edward Bushell, Chief Justice John Vaughan ruled that jurors could not answer questions of law but courts could not answer questions of fact. Thus, in Anglo-American courts today jurors and not the court (unless it is a bench trial) assess the credibility and force of evidence during the process of proof. As the right to cross-examine opposing witnesses became established, Sir Matthew Hale could claim (in 1739) that the adversary system, involving the parties in contention, their counsels, and the court, was unmatched for ‘beating and boulting the truth’. (As against this, the twentieth-century legal realist Jerome Frank was to compare adversarial methods to throwing pepper in the eyes of a surgeon.)

Interest in rules governing the admissibility of evidence also emerged as the adversarial system developed. Concern about the admissibility of hearsay evidence, for example, arose following the trial of Sir Walter Ralegh in 1603. Ralegh was convicted of treason partly on the basis of evidence having no better status than rumour or gossip, since the source of it was never identified. Rules concerning the admissibility of hearsay date from the

acknowledged injustice in Ralegh's case. Since those times, what are now termed the laws of evidence began to emerge. In one sense these laws of evidence consist of assorted exceptions to a principle of free proof (virtually all evidence admissible), as advocated by Jeremy Bentham and now practised, for example, in Sweden. These laws of evidence have hardly been stationary. They have changed over time and will almost certainly continue to do so in response to continuing debates about their fairness, changes in political climate, and changes in patterns of litigation.

Even if all rules of admissibility were abolished, there would still be concern about what constitutes proof. In discussing evidence and its inferential roles in proof, we encounter matters that are continuing sources of debate among legal scholars, philosophers, probabilists and others. Settlement of any dispute, however it is accomplished, rests at some stage upon arguments based on evidence. Few episodes of litigation, whether criminal or civil, actually come to trial. Thus it would be a mistake to consider the trial as paradigmatic in any study of the properties and uses of evidence. This acknowledged, bodies of evidence encountered in any litigation have certain well-known properties. The evidence is necessarily incomplete, often on important matters. Items of evidence are usually inconclusive to some degree, meaning that the evidence is consistent with more than one probandum, hypothesis or fact in issue. Evidence is often imprecise or vague; we cannot tell exactly what it means. Evidence comes to us from sources which are not perfectly credible. Finally, bodies of evidence usually reveal interesting patterns of dissonance; some items seem to favour one conclusion, others a different conclusion.

These characteristics of bodies of evidence combine to make any conclusion drawn from them probabilistic in nature. Thus, forensic standards of proof involve hedges or qualifiers (discussed in §§4-5 below) that acknowledge these omnipresent characteristics of evidence. Judicial proof, like proof based on incomplete and fallible evidence in other contexts, is probabilistic rather than demonstrative or necessary. There is no forensic standard that requires proof with certainty or beyond the possibility of doubt.

2 The credentials of legal evidence

In the Anglo-American judicial system, a rationalist-empiricist view of the nature of proof in adversarial proceedings has been predominant in the past two centuries. On this view, matters at issue in a dispute are to be proved at specified levels of probability on the basis of evidence that is both relevant and credible or believable. Such a process seems rational, at least with respect to earlier proof methods involving oaths, ordeals or combat, as well as juries composed of adversary witnesses. The empiricism stems from the requirement that proof be based upon evidence observable in some way to those who must render verdicts in disputes. Two of the most prominent rationalist-empiricists have been Jeremy Bentham and, in the USA, John Henry Wigmore.

There is considerable dispute about what constitutes rationality in all of human inference and choice. Regarding evidence and inference, part of this controversy concerns the means by which the probative or inferential force of evidence ought to be assessed and then combined in reaching a conclusion (see §§4-5 below). Choices made by those who participate in settling disputes involve more than evidence, inference and probabilities; they also involve value-related ingredients. In any dispute there are multiple stakeholders including the parties in contention, their advocates, court officials and society at large. Settling disputes is difficult given the competing and often internally inconsistent value systems of these stakeholders. Any pretension to rationality in legal matters appears to involve a seamless integration of matters concerning both the probability and value ingredients of choice as well as the process by which they are combined.

It appears that an item of evidence must have three credentials in order for it to be in any way persuasive during the process of proof. The necessary credentials concern the relevance, credibility and probative (inferential) force of evidence. Of course, no evidence comes with these three credentials already established; they have to be justified by cogent arguments, often having many stages, and by careful judgments (see §3 below). An item of evidence is commonly said to be relevant in a legal dispute if it makes the existence of some material fact at issue 'more probable' or 'less probable' than it would be without the evidence. This is often put subjectively: evidence is relevant if it would cause anyone to change their beliefs about the likeliness of some material fact at issue. We might also say that evidence is relevant if it has some probative force in belief revision. There are no rules in law saying how much force any item of relevant evidence ought to have.

Evidence can be relevant in different ways. It is said to be directly relevant if a chain of reasoning can be formed

from the evidence to a major issue in the case. There are two species of directly relevant evidence: direct and circumstantial. Direct evidence goes in one reasoning step to some fact at issue and, if credible, would settle the matter. Circumstantial evidence, even if perfectly credible, supplies only some but not complete grounds for belief in some matter. But some evidence has only indirect relevance; such evidence is said to be ancillary or auxiliary in nature. Ancillary evidence either strengthens or weakens links in chains of reasoning set up by directly relevant evidence. Generalizations are asserted to license a reasoning step or link. Ancillary evidence bears upon whether or not this asserted generalization holds in the present case in which it is being invoked. For example, we might assert the generalization: 'if a person testifies under oath to the occurrence of an event, then this event probably did occur'. Tests of this generalization, applied to a particular witness, involve ancillary evidence concerning this witness's veracity, objectivity and observational sensitivity. We might say that ancillary evidence is evidence about the strength of other evidence. The relevance-status of evidence obviously depends upon the case at hand; a datum can be relevant evidence in one situation and quite irrelevant as evidence in another.

Suppose an item of evidence whose relevance can be established. The question then is: can we believe what this evidence says? Credibility considerations form the very foundation for all arguments based on evidence; that is, they form the first links in a chain of reasoning. There are different discernible forms of evidence (see §3 below); judgments about the credibility of evidence depend upon what form evidence takes. For tangible evidence, open to direct inspection by fact-finders, such matters as the authenticity and chain of custody are of interest as well as the accuracy of the evidence if it exists in the form of some sensor record such as a photograph or radar image. For testimonial evidence involving the assertions of human witnesses, credibility assessment is quite different. We first need to establish how a person obtained the information they report: (1) by direct observation; (2) at second-hand from another source (possibly hearsay); or (3) by inference from other information (opinion evidence). Like other human characteristics, the credibility of a witness has many attributes. Among the important attributes of witness credibility are veracity, objectivity and observational sensitivity or accuracy.

Assessing the probative force of an item of evidence is a judgmental matter for which there are no legal rules. Many factors enter into such judgments such as the credibility of the source from which the evidence comes, the probabilistic strength of links in chains of reasoning from the evidence, the number of links in the chain, the rareness or improbability of the events reported in the evidence, and the possible influence of other evidence (see also §4 below).

Courts may rule on whether an item of evidence is relevant, but fact-finders must judge the credibility and probative force of evidence. Judgments about any of these three credentials of evidence will naturally depend upon a person's standpoint or frame of reference. Disagreements about the relevance, credibility and probative force of evidence are to be expected in legal and in other contexts. One major reason is that persons having different standpoints, backgrounds, objectives and values will effectively view the same evidence through different perceptual 'lenses'.

3 Structural issues

Analyses of the relevance, credibility and probative force of evidence involve both structural and probabilistic issues. Structural issues arise during the construction of arguments or chains of reasoning to justify these three credentials of evidence. There are several major structural difficulties, the first of which concerns the fact that chains of reasoning we construct often have many links. Each link inserted in a chain of reasoning from an item of evidence to some major probandum or hypothesis identifies a source of uncertainty recognized by the person constructing the chain of reasoning. Both Bentham and Wigmore recognized that there are very few inferences in which a chain of reasoning has just one link. Wigmore applied the name 'catenated' to those inferences involving two or more links. Today such inferences are said to be cascaded, multi-stage or hierarchical; the term 'inference-upon-inference' is also employed. Until recently, there has been scant reference outside the field of law to catenated or cascaded inference.

The second structural difficulty concerns arbitrariness in the construction of a reasoning chain. Two persons may justifiably construct different chains of reasoning from the same evidence to the same probanda; in other words, they take different reasoning routes. They may of course each take reasoning routes from the same evidence to different probanda. The logician John Venn noted that both the number and the labelling of stages of reasoning is often quite arbitrary. Wigmore emphasized that the form an argument takes depends upon who constructed it. In

short, there are no normatively ‘correct’ arguments. This has a distinct bearing on the issue of rationality in inference since more than one argument may be justifiable from the same evidence. Plausibility and the avoidance of *non sequitur*s seem to be our major guides in argument construction. The construction of any argument is in fact a creative act, as is the discovery or generation of evidence and possible probanda in the first place.

In evaluating the credentials of evidence a major structural difficulty in legal and other contexts is that we usually have masses of evidence to contend with. Arguments constructed from masses of evidence can be stunningly complex and, when depicted graphically, they resemble complex networks; they are now in fact called inference networks. Wigmore (in 1913) was the first to study complex inference networks based upon masses of evidence. He devised a graphic scheme for charting arguments from evidence to the ultimate probandum in a case. Modern analysis of Wigmore’s evidence charts shows that his inference networks can be characterized mathematically as directed acyclic graphs. A network is a kind of graph structure containing two basic elements: nodes and arcs. In an inference network nodes represent evidence and interim or final probanda (propositions to be proved); arcs represent probabilistic linkages among nodes. Inference networks are directed because reasoning proceeds inductively from evidence to major or ultimate probanda. They are acyclic because there is no path of arcs from any node that brings you back to this same node; this would amount to being in an inferential loop.

Inferences involving legal disputes tend to be well-structured from the top down. To prove a major fact at issue, at some specified level of probability, certain elements must be established. These elements, called penultimate probanda, stem from substantive law concerning the legal matter at hand. For example, a case of first-degree (premeditated) murder may involve the penultimate probanda: (1) Y was killed; (2) it was defendant X who killed Y; (3) X intended to kill Y (it was not an accident); and (4) X formed this intent beforehand. In essence, each of these penultimate probanda serves as a touchstone for determining the relevance of evidence.

Attention to structural matters provides a basis for categorizing evidence without regard to its substance or content. Jurists, and perhaps historians, must be prepared to evaluate evidence having virtually any conceivable content or substance. The relevance and credibility credentials of evidence discussed above assist first in the identification of distinguishable forms of evidence. We ask two questions: (1) how does the evidence stand in relation to the person evaluating it? and (2) how does the evidence stand in relation to the major facts at issue?

Answers to the first question allow us to identify properties of evidence that govern how its credibility is to be assessed. Discussed in §2 above are two of the basic forms of evidence: tangible and testimonial; there are others. In some cases evidence expected but missing can itself be taken as evidence. Missing evidence is not the same as negative evidence, the report of the nonoccurrence of an event. It has been recognized in law for quite some time that the non-production of evidence invites the inference that the evidence is unfavourable to the interests of the person who refuses to provide it. Other evidence comes from various authoritative sources such as almanacs and various tables of physical or chemical phenomena. In addition, there are certain facts that can be accepted without further proof, such as: strychnine in sufficient doses is lethal. Information from authoritative sources and certain accepted facts may be judicially noticed by courts and accepted without further proof. Answers to the second (relevance) question above allow us to identify evidence as being direct, circumstantial or ancillary (as noted in §2 above). Combinations of answers to these two questions allow us to categorize any evidence. For example, we may have tangible evidence that is circumstantial on some matter at issue, or have testimonial evidence that is indirectly relevant or ancillary.

In purely structural terms, we may also identify recurrent combinations of evidence. Dissonant evidence comes in two basic forms: contradictory evidence and conflicting evidence. Contradictory evidence involves events that cannot happen together, in which case we naturally look to the credibility of the sources from which it comes. Conflicting evidence, however, concerns events which seem to favour different probanda or hypotheses but which could possibly occur together. In resolving such conflicts we also look to the credibility of our sources; but we must also consider the reasons why we say the evidence is conflicting. Perhaps we could explain away this apparent conflict with better understanding of the situation at hand. Harmonious evidence also has two basic forms: corroboration and convergence. Two forms of corroboration can be discerned. In one case, we have successive reports of the same event. In another case we have ancillary evidence that favours the credibility of a source reporting a certain event. Convergent evidence involves different events we believe to favour the same probandum or hypothesis. Finally, some combinations of evidence exhibit synergism in the sense that one item of

evidence seems to enhance the probative force of another. In other situations, one item of evidence may seem redundant, and thus have less inferential force, when considered in light of other evidence.

4 Probability and the probative force of evidence

Evidence is relevant if it has some probative force on material facts at issue. How much probative force an item or body of evidence has can only be graded in probabilistic terms; this is a consequence of evidence being incomplete, inconclusive, imprecise and not completely credible (see §2). There are no legal rules that prescribe how the probative force or weight of evidence should be assessed; such assessment calls for judgments on the part of jurors or judges (in bench trials). The task of weighing evidence rests upon the ordinary or common-sense reasoning ability that fact-finders are credited with possessing. Since the early 1600s, when interest in probability calculations emerged, there have been intermittent attempts to determine the extent to which mathematical probability theories can offer any guidance in the task of weighing and combining evidence in legal affairs. Some of the very earliest probabilistic analyses involved study of the relation between the probative force of testimony and the credibility of its sources.

Probabilistic analyses of the task of assessing the probative force of evidence have drawn a mixed reaction on the part of evidence scholars in law. One reason is that the theory of probability stemming from the work of Blaise Pascal (§5) in the seventeenth century is rooted in enumerative processes such as those encountered in determining probabilities in games of chance or in replicable statistical analyses. Inferences in law, however, usually concern singular or unique events that are not replicable or subject to enumerative analysis. In the conventional or Pascalian theory of probability, the one most persons learn about on first exposure to the subject, probabilities are taken to be numbers between zero and one (inclusive) that are additive across mutually exclusive events. A process called conditioning allows for the revision of a probability in light of new evidence. A consequence known as Bayes' rule, consistent with the properties of Pascalian probability and the manner in which a conditional probability is defined, emerges as a canon for probabilistic reasoning based on evidence. This rule has been the subject of controversy among philosophers, probabilists and statisticians. Some, but not all, believe Bayes' rule to be the canon for inductive and probabilistic inference (see Probability theory and epistemology).

Pascalian probability is subject to a variety of interpretations in addition to those involving aleatory (chance) or relative frequency (statistical) situations. One alternative, congenial to the application of Bayes' rule, involves viewing Pascalian probability in an epistemic sense to indicate a person's degree of subjective or personal belief, based on evidence, that a certain proposition is true or that some event has occurred or will occur. This interpretation allows singular or unique events to be graded probabilistically. Terms in Bayes' rule called likelihoods and likelihood ratios form one very useful way of grading the probative force of evidence. Study of these ingredients of Bayes' rule allows the capture of a wide assortment of evidential subtleties that arise in the task of assessing the probative force of the various forms and combinations of evidence mentioned in §3 above. At the same time, however, various difficulties with a Pascalian interpretation of probability, and the use of Bayes's rule, have led to some well-articulated alternatives to the Pascalian system of probability. Study of the relative merits of these alternative formal systems forms one basis for the 'probability debates' now taking place among scholars of evidence in jurisprudence.

One natural question concerns why we should expect the Pascalian system, rooted in enumeration, to be necessarily adequate in capturing all observed attributes of the epistemic probability judgments so often made regarding singular or unique events? The additivity of probabilities in the Pascalian system requires a complete commitment of belief to an event and to its complement. For example, if on evidence we believe probandum H has probability 0.8, we must also say we believe that not-H has probability 0.2. In recent years a formal non-additive system of probabilistic reasoning called 'belief functions' has been developed that allows a person to be uncommited in various ways in making epistemic probability judgments. This system, also rooted in much earlier studies, allows capture of a variety of credal states that are elusive to Pascalian probabilities. For instance, belief functions allow us to distinguish between lack of belief and disbelief, to capture the concept of ignorance as lack of evidence, and to give a more precise meaning to the term 'doubt'.

Since the time of Francis Bacon (§4), it has been recognized that inductive reasoning can involve the eliminative rather than the enumerative use of evidence. In recent years, a system of probabilities called 'Baconian probabilities' has been developed that is expressly congenial to induction by elimination. In eliminative induction

alternative probanda or hypotheses are subjected to a variety of different evidential tests, each one designed to eliminate at least one of the hypotheses. A hypothesis surviving our best attempts at variative elimination has the highest Baconian probability. A distinguishing feature of Baconian probability is the importance it places on the completeness of coverage (or the sufficiency) of evidence. The weight of evidence in Baconian terms depends not only upon questions we have answered by evidence but also upon recognized questions we have not yet answered with evidence. One very important element of the current probability debates concerns the extent to which judicial proof may be eliminative in nature.

In the process of judicial proof, probability statements are made in linguistic terms rather than in numbers. Thus we have such forensic proof standards as 'beyond reasonable doubt', 'clear and convincing evidence', and 'balance of probabilities'. Attempts to cast these standards in precise numerical terms inevitably fail; these forensic standards acknowledge the imprecision latent in so much of legal reasoning. The common-sense generalizations we assert to license stages of reasoning are stated imprecisely. For example, we assert: 'persons who utter threats *often* intend to carry them out'. Since no one compiles any relevant statistics on such matters, we use imprecise linguistic qualifiers such as 'usually', 'often', 'frequently' or 'probably'. Evidence can also be imprecise; we may have evidence reporting that a witness has not very good eyesight or that it was very dark when the witness made an alleged observation. There is now in existence a well-developed formal system of fuzzy inference and fuzzy probability that permits some very precise ways of coping with the imprecise or fuzzy linguistic variables so often encountered in judicial proof. This system rests upon a multivalued logic instead of the two-valued logic forming the basis for other formal systems of probability (see Fuzzy logic §3).

It does appear that the task of assessing the probative force of evidence is far too rich an intellectual activity to expect that any single formal system of probability can capture all of this richness. Each one of the formal systems just discussed is informative and resonates to some but not all of the important attributes of the task of weighing evidence.

5 Inference from a mass of evidence

Inference from evidence in judicial proof is embedded in the further process of choice. Following a trial, courts and jurors render verdicts and decide upon consequences. In other forms of settlement choices are made by both sides during the process of negotiation and bargaining. The inferential element in all such decisions involves the very difficult task of drawing conclusions from masses of evidence in which all the forms and combinations mentioned in §3 above are likely to be represented. There are no laws of evidence telling fact-finders how to combine all the evidence in reaching a final conclusion. Although the various probability theories discussed in §4 offer suggestions about how such complex inference tasks might be decomposed to simplify them, the actual inferential judgments made by fact-finders are holistic and are neither decomposed nor otherwise assisted by means of any formal theory concerning the combination of evidence. There is now an abundance of empirical research on strategies that fact-finders employ in drawing conclusions from masses of evidence.

The only inferential guidelines offered in the laws of evidence concern belief intensity thresholds required for verdicts in criminal and civil cases. These belief thresholds exist in the form of the imprecise or fuzzy forensic standards of proof such as 'beyond reasonable doubt' (in criminal cases) and 'balance of probabilities' or 'preponderance of evidence' (in civil cases). One element of the current 'probability debates' concerns whether or not contemporary theories of probability offer ways of adding precision in prescribing these forensic standards.

Legal hermeneutics

Legal hermeneutics studies the interpretation and meaning of written law. By way of contrast with the related discipline of forensic rhetoric, the study of oral argumentation and persuasion in court, legal hermeneutics is best defined as a textual discipline which dates back to the classical codifications of Greek and Roman law. While the term hermeneutics is derived from the messenger god Hermes and is used by Aristotle as the title of a work concerned with the logic of interpretation, Peri hermeneias, legal hermeneutics really only developed with the growth and medieval reception of Roman law. The Roman legal tradition was pre-eminently a tradition of ius scriptum *or written law, of codes and codifications. The custody, interpretation and transmission of the great texts of Roman law gave rise to an exemplary discipline of hermeneutics. Its task was that of preserving, collating, translating and applying the archaic, foreign (Latin) and fragmentary texts of the legal tradition to contemporary and vernacular circumstances far removed in time and space from the original contexts of the written law. In later eras and particularly in periods of crisis or renewal of the legal tradition, the problems of text, interpretation and meaning in law have led to the revival of the concerns and traditions of legal hermeneutics.*

1 1 Law, philology and hermeneutics

The first meaning of the term 'hermeneutics' is one which derives from the function of the god Hermes, who was said to have delivered the messages of the gods to the mortal realm. Hermes translated the divine idiom into human speech and thus became, together with his Latin form Mercury, the emblem of the task of translation between different orders, times and places. In so far as Hermes carried and communicated the words, the eloquence and the authority of the gods, his task was always tied to the question of law. In its broadest definition, hermeneutics identified the problem of meaning and interpretation with that of access to the divine source and spirit of all human law. Hermeneutics thus identified the art of interpretation with that of unveiling and translating the alien or hidden message of the divine or distant author of the laws.

While the dominant model of post-classical literary hermeneutics was theological and concerned the exegesis and interpretation of the Scriptures and the canons or laws of the Church, a parallel tradition of legal hermeneutics existed. The secular model for legal hermeneutics developed initially and somewhat paradoxically around the two main codifications of Roman law, namely the Twelve Tables from the fifth century BC and the sixth-century *Corpus iuris civilis*. These codifications, although vastly different in style, both endeavoured to state a divinely inspired and absolute body of law in a written form which would preclude the need for interpretation. The Twelve Tables dealt with disputed points of law and aimed, through the use of writing, to take the resolution of such issues out of the hands of the pontiffs, the interpreters of the law. So too the Eastern Roman emperor Justinian promulgated his massive codification of Roman law with the accompanying injunction that 'no-one - neither those who presently practise jurisprudence, nor those who will practise it in future - may presume to compose commentaries on these laws', a ruling which is explained slightly later by means of the equation of interpretation with perversions (*perversiones*) of law. The jurist or practitioner of legal hermeneutics was thus originally to know and obey the law rather than to construe it, precisely because its authority was far greater than that of any interpretation.

Hermes was also, however, a thief: he stole from the gods by virtue of taking their words and presenting them in secular and novel contexts. The art of legal interpretation also borrowed from this metaphor of theft of meaning in allowing that passage of time brought with it the decline or decay of law and change in the circumstances of its application. Where circumstances had changed or time had rendered the written law less appropriate to novel contexts, the jurist had to use first fiction and then later analogy to apply it. In both circumstances, whether through the fiction of treating the litigants 'as if' they fell within the written rule, or through analogy with the clear meaning of the text, the interpretation was subordinate to the text of law, the unwritten meaning an implication or logical inference from the authoritative text. The art of hermeneutics thus acted covertly to supplement the written law and to legislate new meanings in the guise of textual reconstruction. It stole the power of the lawmaker but it did so under the veil of observance or in the form of the self-effacement of the juristic interpreter.

In its classical periods, and particularly during the medieval reception of Roman law or 'twelfth-century revolution' in interpretation, legal hermeneutics took the form of a practical exercise in the philological

reconstruction of the 'true' or literal meaning of the texts of law. Constrained by the prohibition upon commentary, the interpreter of the law was restricted to the task of providing grammatical glosses and word-by-word explanations of the rules of law. Their task was to harmonize and systematize the archaic and fragmentary textual inheritance of law and through understanding it in ever more profound detail find ways of applying it to the circumstances and contexts of a later age. The glossator was the ideal type of the legal interpreter, an erudite but faceless technician of meaning, a philologist of law who purported to reconstruct and harmonize the terms and rules of written law without ever interfering or interposing between the letter of the law and its destination. In this form, hermeneutics was a discipline which guarded over both tradition and text, an art of custody and of an esoteric and exclusory knowledge of ancient rules or laws.

2 2 Hermeneutics and jurisprudence

The figures of Hermes and Mercury are also suggestive of passage and of turnings, of sleight of hand and the flight of words: Hermes and Mercury both guard and admit, conserve and create. The other face of legal hermeneutics is associated with the speed and slippage or transition that is associated with a law that was always conceived as Janus-faced or split between its divine and human sources. Hermeneutics was thus also associated with the magic or art of legal representation and with words of law, with Coke's *vocabula artis*, which hid behind their vulgar surface a thesaurus of artistic meanings and erudite truths. Hermeneutics was in this sense also always potentially a political and interventionist practice in which the interpreter of law would create new meanings and invent new applications for the cold prose, tired words or dead letters - Bacon's *litera mortua* - of written law (see Common law §2).

This stronger and more modern sense of legal hermeneutics developed as a reaction against the glossatorial tradition and came about primarily through the rediscovery of the classical tradition and law in the Renaissance. Legal humanism pilloried the glossatorial tradition of unthinking or 'imbecilic' reverence for the post-classical compilation and interpolation of Roman law and returned rather to the surviving sources of Roman law itself. In place of the glossators' slavish observance of textual letter and rule, humanism sought to comprehend the law in terms of the context of its historical enunciation. Roman law, according to François Hotman, was not an adequate model for contemporary law; rather it represented the property interests and privileges of the Roman bourgeoisie and should be understood in terms of (and restricted to) that social and political context. The rules of legal hermeneutic method devised by the humanists and associated particularly with Jacques Cujas, Andrea Aliciato and François Hotman on the Continent and with Christopher St German and later Sir Francis Bacon and Sir Edward Coke in England, entailed a much stronger philological sensibility and rhetorical awareness.

The exemplary form of Renaissance hermeneutics was the treatise on *Digest* 50.16, *De verborum significatione* (on the meaning of words) (see Roman law §2). While such treatises were still commentaries upon the classical Roman sources of law, and upon the terms and rules of the textual tradition, they went far beyond the singular text of the earlier tradition and expounded theories of interpretation which greatly exceeded the style of the gloss both in method and in scope of disciplinary reference. The first feature of such hermeneutics lay in the conscious comprehension of law as tradition and interpretation, as both written and unwritten, as sense and reference. The key interpretive maxim in relation to this approach was *Digest* 1.3.17 (Celsus): '[t]o know the law is not to know the words of the law, but its force and power [*vim ac potestatem*]'. In other comparable formulations the words of the law were contrasted to its 'root reason', 'intention', 'cause', 'rationale', 'purpose' and 'true sense'. The radical alterity of the past and the fragmentary character of its textual remains both forced the jurist towards a critical hermeneutics which could add to the literal meaning a covert sense or spirit of law, a meaning which could only be discovered by linguistic inference or supplementation, by reading between the lines *subauditio* or *subintellectio*. In short, the function of such a hermeneutics was to supplement the paucity of the textual remains of law and to recreate a fuller meaning by use of a wide array of philological, historical and linguistic techniques of reconstruction.

The second striking feature of hermeneutic jurisprudence lay in the methodologies developed to accommodate and expound the unwritten meaning or '*labile ratio*' of the legal text. Once it was explicitly recognized that the terms and rules laid down in antique texts could never apply directly, or without interpretation or 'interposition', to the linguistic context and social circumstances of contemporary disputes, the task of hermeneutics became that of finding something more in the law than was merely written. To this end the treatises on *De verborum*

significatione developed an extensive array of techniques of interpretation drawn from a wide variety of other disciplines. History, philology, logic and rhetoric were the principal sources for extension and innovation in relation to written rules and allowed for the systematic development of techniques of contextual interpretation and supplementation. While there was no one standard set of rules for the construction of legal meaning from between the lines of the law, a series of methods and contexts were developed which still play a role in the contemporary jurisprudence of interpretation. Most notably, construction of textual meaning would start from philological criticism of the text itself and would move to reconstrue it by reference to what may be classified synoptically as linguistic, legal and rhetorical contexts. The linguistic context would refer to etymological analysis as well as to grammatical rules of construction. The legal context refers not simply to the use of analogy in the extension of rules but also to the need to relate disparate rules and maxims, customs and local laws, to the specific text subjected to interpretation. The rhetorical context, finally, referred not only to the various forms of figuration by which meaning changes according to context and use but also to specifically legal senses of the intention of the author of the laws (*mens legis*) and the force or reason of their utterance.

3 3 Philosophy of language, precedent and hermeneutics

The various post-Renaissance revivals of legal hermeneutics have tended to coincide with crises and renewals of the legal tradition, associated most particularly with movements for codification or other reforms of law. The nineteenth century in particular witnessed a pan-European resurgence of hermeneutic method in the arts in general and in jurisprudence in particular. The peculiar concern of the new legal hermeneutics was that of the place of language and of meaning within the efflorescence of legislation and administrative regulation that accompanied the growth of the modern industrial state. While the method and models of textual understanding were still predicated upon the earlier theological and juristic conceptions of construction and interpretation, the more secular concern of legal philosophy was that of the place of meaning within the development of a science of law.

One model of hermeneutics returned to the glossator's exegetical conception of absolute and authoritative texts. The highly restrictive hermeneutics which developed around the *Code Napoléon* (1804), for example, asserted that all meaning was to be drawn from the legal text and from nowhere but the text. In a similar vein, Jeremy Bentham in England believed that codification of the law could take the problem of legal interpretation out of the arbitrary jurisdiction of the common law judges and return it to the people in the form of simple, clear and comprehensive textual expressions of the rules of law. Codification, however, was only ever a temporary solution to the hermeneutic problem of interpretation and passage of time, change of context and of circumstance. The indeterminacy of language inevitably raised again the problems of finding unwritten meanings which exceeded or displaced the surface sense or letter of the law. What was new about the post-Enlightenment hermeneutics was that philosophy of language and particularly phenomenology, social science, linguistics and literary criticism replaced the earlier traditions of philology and rhetoric as the principal disciplines to come to the aid of jurisprudence. It is significant, however, that when Hans-Georg Gadamer (§3) or Emilio Betti, arguably the two great hermeneutic philosophers of the twentieth century, turn to the definition of hermeneutics they place law at the heart of the discipline. In Gadamer‘s terms, law is exemplary of the historical problem of writing and it is as central to the proper formulation of the problem of meaning as that of the relation between historical sense and contemporary application, between text and judgment (Gadamer 1976).

The problem of hermeneutics, according to Gadamer, is the problem of law. It is that of creating contemporary meanings out of the antique and alien materials of tradition. The lawyer faces this problem in an acute form, and therefore is forced to resolve it in an exemplary way by reconciling the spirit of the tradition with the needs of contemporary communities. For Gadamer, legal hermeneutics could resolve the problem of the meaning of tradition by understanding the prejudices or pre-judgments by means of which the tradition already governed the contemporary instance. Gadamer's notion of 'the pre-schematisation of our European attitude' draws heavily upon Heidegger's conception of language, and particularly the philosophical language of the Greeks, as a code already imprinted with the metaphysics and the meanings which the subsequent tradition has lived out. For Gadamer and in a somewhat different form for Betti, the prior existence of linguistic meaning did not wholly resolve the legal problem of law-applying acts in the sense that neither linguistic tradition nor precedent could wholly determine the contemporary instance. The hermeneutic conception of understanding (*Verstehen*) also entailed an active sense of the inevitability of the creation and extension of meanings by recourse, in Gadamer's theory, to the spirit of the legal tradition through the hermeneutic unlocking of 'original' meanings and, in Betti's theory, through the use of

reasoning by analogy.

4 4 Critical legal hermeneutics

The problem of precedent and of the frequently disjunctive relation of norms or rules to decisions and to practices has consistently troubled the various modernist attempts to construct a science of law (see Legal reasoning and interpretation). Hermeneutics, and the problems of language and of writing more broadly, were a consistent threat to the jurisprudential systematizers of the common law tradition in particular. Predicated not upon a code but upon a disparate series of statutes, reported decisions, customs, maxims and other borrowings, the claim that law formed a coherent and unitary body of determinate rules was always hermeneutically precarious. While the positivist tradition of jurisprudence on occasion has recognized a certain latitude, *Verstehen* or 'internal attitude', in the interpretation of law as a system of rules, the concept of a legal system has most generally been presented, as for example in the work of the Austrian legal theorist Hans Kelsen, in such a manner as to exclude any strong conception of hermeneutics from the theory of law (see Legal positivism §5; Kelsen, H.).

Historicist and more properly hermeneutic reactions against positivistic and formalistic theories of law were contemporary with their original elaboration. Such reactions to legal science could be broadly speaking conservative, as for example was the German Friedrich Karl von Savigny's historicist legal hermeneutics, which endeavoured at the beginning of the nineteenth century to counter codification with a historical science of law. The other tendency of hermeneutics, however, was more critical and iconoclastic. What may be termed critical legal hermeneutics, drawing upon disciplines as diverse as sociology, linguistics and psychoanalysis, denies that there is any unitary body of law at the level of social systems and equally disputes the possibility of 'true', objective or singular legal meanings at the level of textual interpretation. The earliest political expression of a species of critical legal hermeneutics came with the US legal realist movement in the elite law schools of the USA in the early part of the twentieth century (see Legal realism §2). Concerned primarily with issues of statutory interpretation and the decisional practices of the courts, realist legal hermeneutics asserted the priority of judgment or court practice over written norms and so either implied or directly asserted the indeterminacy of legal meaning and the creative role of all law-applying acts.

Where legal realism was concerned primarily with drawing attention to the oral and contingent context of the courtroom and thereby challenged the naïve belief in a text-based science of law, subsequent developments of critical legal hermeneutics have focused almost exclusively on the indeterminacies or undecidability of written law. Variously located within critical race theory, feminist jurisprudence and critical legal scholarship, the contemporary hermeneutic challenge to the objectivity of the legal text is formulated in terms, respectively, of ethnicity, gender and politics (see Critical Legal Studies). Basing itself most broadly upon theories of textual indeterminacy, one of the key goals of critical legal hermeneutics has been to politicize law by evidencing the malleable and discretionary character of its textual practice. The legal text is a species of writing, a performative use of language or *écriture*, and it should be analysed as such before or as well as being consigned to the genre or tradition of legal science. In this respect, critical legal hermeneutics is concerned to treat the legal text as a form of literature and to subject it to the disciplines and dismemberments that the arts now throw in the way of textual meaning. Following the tradition of humanistic hermeneutics, but using contemporary disciplinary idioms, the critical legal endeavour has aimed to link legal language both to the inequity and to the literal and the metaphorical violence of law. Critical hermeneutics is aimed thus at producing an ethics of legal reading and of writing law, an ethics which ideally links text to judgment, word to act and, in its broadest philosophical expression, written law to the constraints of justice.

Legal idealism

The term 'legal idealism' has various meanings. These include: the notion that laws, and the rights and duties they confer, genuinely exist, in which legal idealism is opposed to legal realism; the notion that law is intimately connected with moral or social values, in which legal idealism is opposed to legal positivism; the notion that one can move from certain premises about human reason and will to systematic principles for legal development and decision-making; and the notion that one can derive systematic principles of a similar kind from the requirements of social life. It is also sometimes used to imply too much faith in the capacity of law to solve problems. The enduring issues of legal idealism concern establishing systematic principles for legal development and decision-making.

1 1 The varieties of legal idealism

Legal idealism is a particularly confusing term as it is used of different, and sometimes incompatible, approaches to law. First, and at its broadest, it covers all those theories which regard law as normative or standard-setting, as expressing what ought to be done. Such theories typically treat law as consisting of norms or rules or principles and as conferring rights and duties (see Legal concepts; Norms, legal). Legal idealism, here, is tied to a certain kind of philosophical idealism, since law is seen as the product of some act of mind or will. As such its norms genuinely form part of our world. For most thinkers, this is also the case with the rights and duties to which it gives rise. So understood, legal idealism embraces most, if not all, natural law thinking (see Natural law) and even certain types of legal positivism, such as that of Hans Kelsen. It stands in opposition, however, to other types of legal positivism, for which matters such as rules and duties are at best imaginary entities, with talk about them to be explained away in terms of attempts to predict or promote certain forms of human behaviour (see Legal realism §1).

Second, the term 'legal idealism' is used for theories that regard law as intimately connected with certain specified moral or social values, such as freedom, justice, democracy, cultural evolution or group solidarity. Here idealism is understood in a sense closer to that of ordinary language, where it is tied to the having of ideals. In this context, legal idealism once again covers natural law thinking and also certain other approaches that resemble it. Here legal idealism stands in opposition to legal positivism, where it is claimed that law is to be identified solely by reference to the form it takes or the source from which it comes, with no built-in restrictions as to content or purpose (see Legal positivism).

Third, there is what is known as transcendental legal idealism. A transcendental inquiry is concerned with investigating the conditions under which certain kinds of experience or knowledge are possible. This kind of approach, using the tradition of Kant (§5), was adopted within a group of theories of largely, although not exclusively, German origin. Such theories begin from certain premises about the nature of human reason and will and develop a legal philosophy from them. One of the objects of such a philosophy is to provide a 'scientific', largely in the sense of 'systematic', basis for the development of law and for legal decision-making. The main departure from Kant is in terms of the emphasis that is placed on the social purposes of law.

Fourth, there is what is sometimes called absolute legal idealism, following the work primarily of Hegel (§8). This starts from the premise that there is some absolute idea and argues that history works inexorably towards its fulfilment. Law, in both form and content, reflects stages in the development of this idea.

Fifth, there is historical/social legal idealism. This differs from transcendental and absolute legal idealism mainly by taking the actual nature of social life as a given and attempting to find within it the ideas or ideals to which law-making and legal decision-making should conform if they are to serve it properly.

Sixth, and finally, legal idealism is sometimes used pejoratively for those theories that are thought to express a naïve faith in the capacity of law to solve social problems.

Various points are worth noting about these different kinds of idealism. A theorist may be an idealist of the first kind without being one of the second kind. Kelsen, for example, subscribed to the objective existence of norms but actively sought a pure, that is value-free, theory of law. On the other hand, the third, fourth and fifth kinds of idealism are all value-laden and so are really just particular versions of the second kind. They are, however,

sometimes presented as if they did nothing more than restate the factual requirements of social life. Finally, some thinkers are difficult to allocate, since their theories seem to incorporate elements from more than one of the particular versions.

2 2 Transcendental and absolute legal idealism

The starting point is Kant's distinction between theoretical or speculative and practical uses of human reason. Both are concerned with formulating principles or laws, theoretical reason with what is and practical reason with what ought to be. Both can be pure, in the sense that the principles involved can be arrived at, not by looking to experience, but by looking for the conditions that make such experience intelligible. Pure practical reason is directed to discovering the conditions for moral action. These are found in the laws that humans should set themselves if they are to be free, that is to determine their own wills on a fully rational basis. The actions that ought to be performed under such laws are duties. When it comes to actual human behaviour, however, duties may be performed under two different sorts of motive. The first sort is internal, where the very existence of the duty is the motive for the action, in which case the law is an ethical one and the duty a matter of virtue. The second sort is external, deriving from law in the juridical or legal sense, where conformity may be brought about by other types of compulsion and the duty is a matter of right. For Kant, however, juridical law, in the form of positive or statutory right proceeding from the will of a legislator, should be confined to enforcing perfect duties. Such duties are primarily concerned with the avoidance of wrongdoing to others, in the form of interfering with their freedom. Justice is thus seen as the sum of the conditions under which individual wills can be conjoined in accordance with a universal law of freedom.

Fichte (§4), though a disciple of Kant, departed from certain of his ideas. One such idea was that there are 'things-in-themselves' which are unknowable, our knowledge being limited to the structure we impose on what appears to us in the course of our experiences. Instead Fichte sought to construct experience from the activity of the conscious self. By discarding the possibility of any reality beyond mind and the objects of experience, he paved the way for the development of Hegelian absolute idealism. His legal philosophy, too, started from the way in which self-conscious beings 'think themselves' and, in parallel with Kant, Fichte saw this as involving them ascribing freedom both to themselves and to others. In so far as the individual respects the freedom of others as if it were absolute, the individual acts ethically and achieves spiritual freedom. Law, however, only requires individuals to limit their freedom to the extent necessary to secure the equal freedom of others. It provides the compulsion by which the duties so generated can be enforced by others as rights. Fichte went further than Kant, however, in terms of the types of rights that should be afforded, extending these into the economic sphere.

Hegel's legal philosophy concentrated on the way in which the free and rational will embodies or objectifies itself in the world in the form of institutions, so proceeding towards a reconciliation with the universal will. It does so at the level of abstract right, involving the rights and duties of human beings as such and covering property, contract and wrong (both civil and criminal); morality, which is the rational will directed towards its own development; and the ethical life, which is a product of the dialectic between abstract right and morality. The ethical life itself begins with the family. To this is counterposed civil society, involving law and the administration of justice. Both are brought together in the state, in which individuals realize their true universal wills, finding, in their duty, their substantive freedom. Much of Hegel's importance for legal theory, however, lies in his philosophy of history, according to which there is a continuing progression towards absolute freedom, stages in this progression being represented by particular states at particular times.

These thinkers, for whom legal philosophy was simply an aspect of their more general philosophy, had considerable influence on the ideas of those concerned more directly with law. For example, Stammler developed a theory of justice obviously indebted to the ideas of Kant. He distinguished between the notion of law as a particular kind of human volition, as an inviolable, sovereign, combining will, and the idea of law, which is concerned with achieving the perfect harmony of individual purposes, with attaining the social ideal of a community whose members will this freely as an end. From this Stammler derived his four principles of just law: two of respect, limiting the manner and extent to which members of the community can impose their own will on others; and two of participation, limiting the manner and extent to which any member may be excluded from the benefits of community life. The first principle in each set is to do with the avoidance of arbitrariness; the second is to do with treating others in a neighbourly way. In considering how these principles might be applied in practice,

he constructed a model for just law, involving a special community whose actual regulations and the conflicting claims under them are ‘laid before the judgment of the principles of just law’. Natural law thinking, he argued, erred not so much in its method as in claiming universal validity for the rules produced by that method, since this ignores the fact that everything to do with human wants and the way they are satisfied relies on experience and so is subject to constant change.

Del Vecchio also drew a distinction between the notion or concept of law and the idea of law, but developed it in a different manner. In effect he equated the concepts of law and justice and treated them, like Fichte, as derived from the need for reciprocity. He regarded the parallel ideas, however, as more than merely an expression of the preconditions for fulfilling some social end. In his view, the idea of justice has a content which springs from the human conscience. Law is to be seen, in the manner of Hegel, as the progressive realization of justice, the recognition of the absolute value of the personality and the equal freedom of all. Del Vecchio’s combination of Kantianism and Hegelianism was not particularly new. It is, for example, to be found in the writings of the Scottish jurist W. Galbraith Miller in 1884. Del Vecchio’s later works showed a greater move both towards the ideas of Hegel and away from Kantian individualism into corporatism and nationalism. A similar change is to be found in the ideas of Binder, both he and Del Vecchio becoming apologists for political developments in Germany and Italy respectively.

3 3 Historical/social legal idealism

One theorist who attempted to address both the actual nature of social life and the way in which it changed through history was Kohler. In common with Jhering he saw law as a means to a social end but differed from him by rejecting social utility as a criterion. Like Hegel, he saw history as the unfolding of an idea but argued against him that its progress was neither necessarily visible nor logical. Kohler identified the idea as that of civilization, by which he meant the increasing capacity of humans to control both external, and their own, nature. Law has the dual function of serving the needs thrown up by the current state of civilization within a society and of fostering its development. In consequence, what he calls ‘jural postulates’, allowing the law to cope both with differing rates of change and its own fixity, must be developed (see Pound, R.). Kohler arguably had absolutist tendencies to the extent that he identified a single ideal, civilization, and treated law as something that should foster it. (For a different view of the relation between law and cultural values, see Radbruch, G.)

Other thinkers concentrated directly on social life. For example, Duguit saw social solidarity as both a fact and a requirement of social life and law as both an aspect and a requirement of social solidarity. Gény was critical of Stammler for failing to show how his principles of just law might be applied to concrete problems. In a type of natural law thinking, he turned to identifying what will affect any body of positive law - namely factors of a physical or psychological and of a historical kind, general considerations of rationality, and the values embraced by the civilization concerned. The lawyer must take account of what is given in this way, applying his technique to fashion law according to the needs of social life. Interpretation is thus seen as a creative activity and the judge should be informed by *libre recherche scientifique* (free scientific research).

A parallel development in Germany was that of *Interessenjurisprudenz*, which, in the writings, for example, of Heck, argued for the application of a proper sociological method to legal problems. Following Jhering, this was held to involve the identification, classification and balancing of interests, of both a material and an intellectual kind. A much more radical approach, sponsored by theorists such as Ehrlich and Kantorowicz, was that of the *Freierechtslehre* or ‘free law’ school, which advocated the maximum possible recourse to justice and equity in legal decision-making.

4 4 An overview

Legal idealism, in all its guises, runs up against the much broader philosophical question of the relationship between fact and value. Idealist theories are criticized, no matter which way they appear to move, for failing either to bridge the gap between the two or to show that there is actually no such gap to bridge. In the legal context, idealist theories follow different paths in trying to overcome these criticisms. While admitting that facts and values are of a different order, they may variously try to show either how legal norms can, none the less, form part of the world of fact or else how they are somehow required by or derivable from facts. Alternatively, they may effectively deny the distinction, arguing that legal norms, at least those comprising the natural law, exist as a

matter of moral fact. Among the most interesting more recent attempts to root norms in social fact is the 'institutional theory of law' of MacCormick and Weinberger (see Weinberger, O.; Institutionalism in law §4). Habermas' 'theory of communicative action', offering a transcendental argument anchored in the intuitive knowledge of competent members of modern societies, provides a different approach to the same problem and one of equal relevance for legal theory.

Legal positivism

Legal positivism is the approach in the philosophy of law which treats 'positive law' - law laid down in human societies through human decisions - as a distinct phenomenon, susceptible of analysis and description independently of morality, divine law or mere natural reality. It shares with philosophical positivism the aim of dealing in facts, but these are facts about legality and legal systems. Insistence on the distinctness of positive law has been integral to the 'rule of law ideal' because of the aim of clear law applied by neutral legal officials. However, debates about positivism have been marred by a degree of conceptual confusion: positivism often appears to mean something different to its supporters and to its enemies, and many attacks are launched against straw men. Consequently, much depends on the definition of legal positivism that is used.

Attempts have been made to put some order into the discussion. Consider, for instance, H.L.A. Hart's list of meanings of legal positivism (which cumulatively count as features of positivism): (1) law as human commands; (2) absence of any necessary connection between law and morals; (3) the study of law as meaning, as distinct from sociology, history and evaluation; (4) the contention that a legal system is a closed system, sufficient in itself to justify legal decisions; (5) non-cognitivism in ethics (Hart 1958). Norberto Bobbio's list is shorter and more orderly, but at first sight not too different (Bobbio 1960): legal positivism has been conceived as: (1) a neutral, scientific approach to law; (2) a set of theories depicting the law as the product of the modern state, claiming that the law is a set of positive rules of human origin, and ultimately amounting to a set of statutes, collected in legal systems or orders; (3) an ideology of law that gives a value to positive law as such, implying that it should always be obeyed. However, in this list, unlike Hart's, the 'meanings' cannot be added together, the first and last being incompatible. The connection between the three points is as follows: for positivists the theories of Bobbio's second point (law is made up of rules produced by the state) yield a scientific and value-free approach to law; for the adversaries of legal positivism they yield only ideology, that is hidden value judgments in favour of the power of the State.

The shortest way to understand what is at issue in these abstract discussions is to proceed by contrasting legal positivism with its main critics' approach to law. It is noteworthy that on this point legal realists and natural law theorists, although starting from different and even opposite points of view, agree in concluding that legal positivism is an ideological, covertly evaluative, thesis.

1 Positivism versus natural law theory

One of the basic ideas of legal positivism is the separation of law and morals: according to positivism defining what the law is should be kept separate from deciding whether it is just or unjust, good or evil. This is the basic conflict with the iusnaturalists (natural law theorists) who argue that describing the law necessarily requires moral value judgments and choices (see Natural law §§1, 4). Yet, positivism's other main opponents, legal realists, who accept the positivistic aim of a value-free description of law, none the less argue that the positivistic 'formalist' approach is itself contaminated by hidden unrecognized value choices, and therefore that legal naturalism and positivism are really the same. Natural law theorists, taking positivists at their word with a vengeance, often group all their adversaries, including realists, together under the common label of positivism (meaning a value-free approach to describing the law), the lack of what they believe to be a proper understanding of the vital role played by morality in the life of law (Weinreb 1978; Fuller 1958).

Therefore, a little time spent on conceptual clarification will not be wasted. Glanville Williams proffers the most radical answer to this kind of conceptual question about competing definitions: 'Everyone is entitled for his own part to use words in any meaning he pleases: there is no such thing as an intrinsically "proper" or "improper" meaning of a word' (Williams [1945] 1956: 134-6). However, while Williams' thesis is a good antidote to philosophical verbosity, it is a little too simplistic. Not all conceptual discussions can be solved merely by arbitrary definition. In fact, concepts are fragments of theories; when we examine the concept of law in legal positivism, we are looking not just for the meaning of a word but also for a theory which will offer the best approach to legal problems and eventually to the final practical problem of obedience.

So, what is at issue in positing that the 'is' of law can be identified separately from any 'ought'? It means that nearly all positivists replace the moral commitment to justice (however this is defined), which is at the basis of the

iusnaturalistic account of the law, with the aim of a value-free description of effective legal systems (however this is gauged). In other words, effectiveness thus replaces justice in the positivistic conception of law (Hart 1961; Kelsen 1945). Critics of positivism may be forgiven for thinking this to be a rather perverse attitude, making it all too easy for positivistic lawyers to neglect their (moral) duty to take a moral stance towards law. This is sometimes called the '*reductio ad Hitlerum*' of positivism, which is accused of preaching acquiescence to every (effective) law, even when it is as morally evil as Nazi law. This charge is, in turn, firmly rejected by positivists, who observe that something can only be rationally judged and valued if we first know what it is. This is precisely Bentham's basic distinction (see Bentham, J.), which is at the origins of legal positivism, between censorial and expository jurisprudence (Bentham 1977). Many positivists will also add that we gain nothing but confusion in insisting, as natural law theorists do, that unjust laws are not really laws (*lex iniusta non est lex*).

However, natural law theory is saying more than that; otherwise its more dismissive critics would be right in saying that naturalists are merely engaged in a vain battle of words. Iusnaturalists maintain that the law cannot be individuated, described, interpreted or applied unless we continuously make use of moral values and moral choices (Finnis 1973): a normative element is part of the basic choices in the very description of the law. Hence, some naturalists would argue that this should also be a defensible ethical choice, rather than the morally inadequate positivistic standard of effectiveness. In any case, the positivistic attitude, so its critics would argue, leads not to empirical science but, rather, to the moral choice of conformism, an attitude to which lawyers are all too easily prone and which should not be encouraged further.

The positivist might reply that this kind of conformism is indeed an essential part of the rule of law, the ideal embodied in many contemporary legal and political institutions, that power be conferred, controlled and exercised through general rules only (Scarpelli 1965; Fuller 1958). This ideal is a component of all the basic institutions of contemporary Western states, where a legislative body is supposed to make general laws (statutes), while different bodies (the judiciary, the administration) apply them, within the limits of powers granted to them by other legal rules (rules of competence, procedural rules) (see Fuller, L.L.). It is obvious that this ideal is based on, at least, judicial compliance to law and, more widely, obedience of the subjects who fall under law or seek to use it. It is equally obvious that only in so far as it is possible to have an objective knowledge of the meaning of such laws does the whole enterprise make sense; only then will law's reality match the appearances. Legal positivism purports to provide a model of such an objective knowledge, of a legal science conceived as the study of whatever rules come from the appropriate sources and authorities. The next question then must be, what exactly is a (legal) rule?

2 Varieties of legal positivism

All positivists think that the law is a set of legal rules, or norms, a belief that is strictly connected to the fundamental value of the rule of law (see §1). Law is conceived as a device for transferring authority and (political) legitimacy by means of rules; legal rules connect individual choices, such as judicial sentencing, to general decisions such as legislation. But, what is a rule? The main versions of legal positivism can be distinguished by their different accounts of what a legal rule is.

The most immediate and common answer is that a (legal) rule is a command. This thesis is typical of early positivism, as represented by the theories of John Austin (Austin 1832). The second answer is that (legal) rules are judgments as in Kelsen's mature legal positivism (see Kelsen, H.). According to Kelsen, legal rules or norms are conditional, hypothetical judgments of the form: if you committed such and such action, then you (legally) ought to be punished (Kelsen 1945). This idea also avoids the main objection to the older ('naïve') positivism of Austin's kind: that law cannot be reduced entirely to commands, which exist only as part of a direct relation between real persons (see Austin, J.).

The Kelsenian version of legal positivism sees a legal rule as a conditional ought-judgment. However, this renders problematic positivism's claims to legal empiricism. The 'existence' of the sentence/proposition 'if you kill you ought to be punished' is totally unaffected both by the fact that a killing has happened and by the fact that the killer is actually punished. This loose connection with facts is a frailty of Kelsen's brand of positivism. The norms or rules in the Kelsenian sense need to be somehow anchored to social facts, so that the Kelsenian positivist may be enabled to distinguish imaginary or ideal law from real positive law. As we shall see below (§4), Kelsen and all modern positivists attempt to solve this problem with the theory of the existence of a legal system.

The later, ‘analytical’, versions of legal positivism, while preserving Kelsen’s idea that the law is of an impersonal and conditional character, try to translate the whole into more empirical terms. Law is seen as a social phenomenon, essentially as meaning and language. These versions of legal positivism claim that a neutral description of the law, which is vital to the ideal of the rule of law, can be attained by treating the law as a language; in fact this later positivism is usually influenced by some form of linguistic philosophy. Typically, Kelsen’s ‘pure theory of law’ is set on these new philosophical foundations; but the rest of the building is left substantially unchanged, and especially so his theory of a legal system. Legal rules and legal systems are now conceived mainly as (sets of) sentences and meanings, which can be neutrally described without having to be accepted or followed. Their empirical existence is thought to be guaranteed by their being an actually spoken language, something provided, therefore, with a social dimension.

However, there is a significant divide between the Continental and the Anglo-Saxon versions of this linguistic positivism. On the Continent, Bobbio (Bobbio 1950) claimed that jurisprudence should follow the ‘modern philosophy of science’ (meaning the neopositivistic version) and translate the language of the law, especially the language of statutes and codes, into a rigorous and coherent and complete language (see Bobbio, N.). By contrast, some years later in England, H.L.A. Hart used the analytical tools of ordinary language philosophy which roots language ‘rules’ in social use. He claimed that legal rules are essentially an abstraction from effective social practices, characterized by a fundamental linguistic element and certain normative uses of language (the ‘internal discourses’) (Hart 1961).

Bobbio’s theory and Continental positivism was also perhaps influenced by a tradition of statutory law (law as command from above). Its major difficulty was, accordingly, to distinguish between positive law elaborated and made rigorous by the efforts of linguistic jurisprudence, and rigorous but non-positive law (which would have meant falling into the arms of legal naturalism). For this task, subsequent Continental positivism has relied heavily on Kelsen’s theory of the basic norm, which is conceived as the linchpin connecting the whole of a legal system, a huge body of words, to social effectiveness and reality. Hart’s positivism is rooted in reality through its concept of rule as social practice, and its version of the basic norm theory has a much less daunting job to do: simply to recognize when rules are part of a legal system, rather than being the sole warranty of their existence.

3 Positivism versus legal realism

Discussion about the nature of legal ‘reality’, the role of language in legal analysis, and the issues of value-freedom are illuminated by considering the legal realist perspective (see Legal realism). This discussion shows another essential aspect of legal positivism. As the name suggests, realists strive to attain the underlying reality of law which, they say, is hidden and distorted by other approaches, such as positivism or naturalism. The European legal realists share with analytical legal positivists the idea that law is language (see §2). Both also accept that, if it is true that legal rules are language, it is also a language that is often ‘misspoken’, so far as official legal rules (especially statutory law) are concerned. However, they draw different conclusions from this fact based on different ideas as to how a language should be described.

The situation here is similar to that of a natural language where the official grammar and lexicon are significantly detached from the living spoken tongue. Positivists could then be compared to the members of a purist academy who, while well aware of how the language is being used, nevertheless maintain that this is not how the language is, but only the way it is (mis)spoken, and that the task of the linguists - by analogy, the positivist legal philosopher - is to tell how a language is correctly spoken and to describe the rules which make up such a language. By contrast, the legal realists are like those linguists who maintain that the only reality of a language is the actual practice of speech; that linguistic rules are, at most, a useful device for summing up these practices and instances of actual use in so far as they are inferred or induced from actual practice. As for the British positivists, while H.L.A. Hart may, at first sight, seem immune from this criticism, most realists are unhappy with his notion that the single legal rule need not be socially effective, provided it belongs to a legal system (see below) which on the whole is effective (see Hart, H.L.A.). Hart’s critics say that this means taking into account lawyers’ image of the law as an ordered whole, rather than the often disordered reality of the law itself. They would also add that all forms of normative grammar are prescription rather than empirical description. Hence the charge that contemporary legal positivists are engaged in surreptitiously upholding official state law.

In the empiricist, language-conscious framework in which this debate is taking place today, the realist attitude looks more attractive. Before reaching this conclusion, however, a key question needs to be considered. The discussion between realists and positivists can be whittled down to the following: how far is knowing what the law is, different from knowing what the law is for its ‘speakers’? To make sense of the ideal of the rule of law, how far should we be able to distinguish what the law says from what (some) people believe it says? In other words, can we say that the intellectual practices of lawyers are a set of cognitive activities with an objective content rather than superstitious beliefs with a hidden social function?

The European realists thus also take effectiveness as the criterion of law but define that in terms of actual use. They maintain that a value-free and scientific approach to law should take into account all and only the effective legal rules, be they in the official book or not, as extracted by means of the punctual observation of legal practice. While no positivist will deny that such an enterprise is legitimate, albeit very ambitious, they will, however, call it the sociology of law. Moreover positivists would insist that jurists, legal officials, as such, need a different kind of knowledge of legal rules, which is what Kelsen called ‘normative science’ and Hart an approach ‘from the internal point of view’. They will need to know what certain rules prescribe not in order to predict legal behaviour, but in order to know how they should behave, in case they accept them. In fact, it could be argued that neither the realistic nor the positivistic accounts of law offer a genuinely sociological empirical explanation, even though both contain some essential reference to social reality. The realist will describe all and only the legal rules which are effective with judges, the positivist will take into account only those legal systems which are effective as a whole, disregarding the fact that some rules exist only ‘on paper’.

4 Legal systems

The debate between positivism and realism brings to the forefront a key concept of legal positivism, that of a legal system. To positivistic jurisprudence, legal systems are both semantic entities and social realities. Legal rules are first of all words and meanings, prescriptions which can be described and understood, interpreted and used to give a normative legal meaning to facts and actions. Legal rules, being language, are also part of the world of social facts. Legal matters are to be decided by means of arguments or reasons taken mainly from within a legal system; these arguments or reasons are, of course, the legal rules. A legal system contains not only the rules which directly govern actions (called ‘primary rules’ by Hart), but also the ‘secondary’ rules, rules about rules, by which the former are ‘serviced’ (recognized, made, changed, applied). Most positivists assume that every legal system implies one supreme rule, containing or summing up the criteria by which all the other rules of the system are recognized as part of the system (basic norm in Kelsen’s theory, rule of recognition in Hart’s) (see §3).

The notion of a legal system explains the ‘formalist’ aspects of legal practice, the fact that law is conceived by positivistic jurists as being both ‘closed’ and ‘self-sufficient’ or, in a sense, ‘complete’. This does not mean that all legal issues must always be argued without referring to non-legal arguments, that is, moral and sociological facts or reasons. It means, rather, that only those reasons recognized by legal systems are compelling and that they should prevail over all the others, which can be used only to fill the gaps in the system (they amount to using discretionary powers).

According to this point of view, a legal system, with its enormous complexity, is not qualitatively different from a single rule. When we accept a single rule, we can use it as a reason for justifying our practical choices. However, this only postpones the problem, as now we have to justify the acceptance of the rule itself. The same happens with a legal system, but on a much wider scale, according to the positivistic conception (Raz 1975). By accepting a legal system we can put off our basic problem for quite a while, but at the end, we shall have to justify our acceptance or rejection of any particular legal system as a guide to our actions. This is sometimes neglected by people engaged in legal practice, who become, so to speak, moral hostages of the internal complexity of a legal system, thus embracing positivism in the third of Bobbio’s senses mentioned above. On the contrary, as we have seen, positivistic philosophers can well claim to be innocent of this particular sin, because of the thesis of the separation of law and morals.

In fact, having substituted effectiveness for justice as a criterion for ascertaining which normative system is law in a certain society, legal positivists will argue that such a choice is made for descriptive purposes only, and is wholly compatible with rejecting such a legal system on moral grounds. Critics of positivism, to be credible, thus have to delve deeper. To be effective, an attack has to be directed against the positivistic model of legal description; thus

some critics argue that a moral bias is already present whenever we try to distinguish a legal system from other kinds of moral and social rules and, equally, when we assume that in any society there is only one such legal system. Others argue that legal systems do not even exist as a social fact, being rather the product of a normative value-laden interpretation of social reality.

This is not to say that the positivist conception, if correct, is without advantages. The process consisting in the use of the mental tool of the concept of a normative system transforms, at least up to a point, the process of reaching a legal decision into a calculus based on known rules. This is precisely what is called ‘the rule of law’ by its supporters and ‘formalism’ by its critics (see Rule of law (rechtsstaat)). But here uncertainties and difficulties as to this representation of legal activity will crop up at many levels. First, we might doubt that the meaning of the words which make up such rules can be ascertained in any objective way at all. This is the classic problem of interpretation. Such objections usually come from non-positivists (see §5). Second, a host of problems is raised by the ‘dynamic’ or ‘formal’ nature of legal systems, and by the connections between legal rules. If a legal system has to be a calculus, then it is a strange kind of calculus which has to refer continuously to external facts - such as the fact that a statute has been enacted by the legislature or that a court has actually issued a decision - in order to complete its own calculations. This difficulty is well recognized by legal positivists themselves (Kelsen 1979). Positivism thus emphasizes that the systematicity of legal systems is different from purely deductive normative systems where the content of individual concrete rules can be deduced from first principles. On the contrary, a ‘dynamic’ legal system requires a continuous input from external facts and decisions; laws are made and abrogated by legislators, not deduced from first principles. Even judicial sentencing is, obviously, not the result of pure deduction from general rules; sentences have to be pronounced by a judge in the course of a trial, and if they happen to be incorrect deductions, so much the worse for logic and legal calculus. The dynamic or formal aspect of law, so it might be argued, is a matter of power and authority rather than of logic and calculus.

The point is not just that laws can be broken. This would not worry the legal positivist much. Laws are made precisely because they are capable of being violated. The point is that the law itself appears to be able to break its own rules, so to speak, as when an unconstitutional statute is considered valid in a legal system unless it is repealed through a special legal procedure, or a legally wrong sentence is legally binding unless it is reversed on appeal (Paulson 1980). That is why the positivistic autonomous ‘calculation’ of legal rules and decisions can conflict with facts and arguments which are not purely external, as they are considered relevant by the calculus itself (as, for instance, the wrong decision by an authority of the system). This is a powerful argument in the hands of the critics of positivism, who believe that the theory of the legal system and therefore the rule of law idea are a disguise for the exercise of naked power; while positivists try and rebut it with the theory of delegated power (Austin) and of discretion (Hart), claiming that discretionary powers are still controlled by the legal calculus, in so far as the external input is allowed and limited by the system itself (Austin 1832; Hart 1961).

5 Interpretation and rights

Uncertainty as to the real ‘closure’ of a legal system will crop up also at the level of words which make up such rules. This of course is the problem of interpretation. Some realists advance an entirely sceptical theory of interpretation (rule-scepticism) in which no certainty is possible. While many will dismiss such extreme arguments as bad semantics, even the most hardened of positivists will feel much less confident when it comes to certain operations within legal systems, or about certain words of legal discourse that express concepts which have a fundamental role in legal arguments, especially words designating (legal) rights.

Rights are easily identifiable as the Trojan Horse by which external material slips into an otherwise apparently closed legal system. Opponents of positivism will then say that this is because such material is not really external to the law to begin with, but is only seen as such by an overly narrow (legalistic, formalist) conception of law and the rule of law. The legal naturalists will claim that this clearly shows that certain moral ideas are a necessary part of the construction of a right (and hence that morality is necessary to the task of describing law). This argument draws formidable support from the Constitution of the USA as interpreted by their courts, which includes several moral principles and makes them justiciable (Hart 1977).

To legal positivists, wholly open-ended interpretation would make the rule of law an empty travesty, for it depends upon the end of certainty. They point to the difference between mere legality and strict legality. The rule of law requires legality in the second sense, which implies not only that legal decisions be taken according to a law, but

also that the words of the law be formulated by positivistic-minded legislators in such a way as to have a relatively determined meaning; and that interpreters must make the maximum effort in good faith to extract such a meaning before resorting to discretion (Ferrajoli 1990).

All this explains the apparently perverse positivistic attempts to 'sterilize' legal rights. If the rule of law in this strict sense has to survive, then rights must be reducible to the words of positive legal rules. Rights must derive from rules and not the other way around.

Most positivist accounts of the theory of legal rights, such as Kelsen's, stress that law must be entirely reduced to legal norms, and that therefore rights and legal institutions must also be so reduced. Ross' legal realist theory of a legal right (Ross 1951) follows the same reductionist line as Kelsen's (see Ross, A.). Legal rights amount to no more than a conceptual facility which merely makes it easier to sum up the underlying legal rules. The difference is that the positivist will say that the content of a right is a set of duties and powers attributed by legal rules, usually statutes, while a realist will say that rights and duties are empty words without any reference to facts, which at most (Ross) are a useful shorthand for describing and predicting the probable behaviour of the courts, and at worst (Olivecrona 1971) are powerful irrational social factors such as people wrongly believing in the existence of rights and being conditioned by such illusions (see Olivecrona, K.).

The opposite position claims that rights contain more than the words of the legal rules which express them; that they contain a normative surfeit, which can be extracted out of them without making new law. In this case rights could be a source of 'new' law which is not new but already there, although sometimes previously unstated and unsuspected. In the last twenty years Ronald Dworkin has moved a brilliant attack on the tenets of legal positivism in its Hartian form. Precisely in the name of legal rights, Dworkin has formulated in a renovated form the traditional theory of normative surfeit, that law cannot or should not be reduced to a set of explicit rules (Dworkin 1978).

The forward line of defence of positivism on this specific front is today held by Neil MacCormick (MacCormick and Weinberger 1986). As all good defences, MacCormick's stance is composed of a counterattack and a retrenchment. Against Dworkin, the basic tenet of positivism, the distinction between describing and evaluating the law, is reaffirmed (in the name of Bentham); the retrenchment is MacCormick's institutional theory of law, where a theory of right still based on rules is advanced, which attempts to make sense, through the concept of institution, of the aspects of legal rights not strictly reducible to already explicit statutory words (see Institutionalism in law §5).

Legal realism

'Legal realism' is the term commonly used to characterize various currents of twentieth-century legal thought which stand opposed to idealism. (Hence, 'realism' in this context ought to be understood not as a body of thought which opposes nominalism, but as an instance of nominalism.) In the Scandinavian countries, legal realism was modelled on Axel Hägerström's critique of idealist metaphysics, and sought ways to account for legal rights and duties without presupposing or postulating the existence of ideal objects or entities. In the USA, legal realism evolved as a critique of the idealism implicit in the vision of the common law which was promoted by C.C. Langdell, first Dean of the Harvard Law School, and in the laissez-faire *ideology of the late nineteenth- and early twentieth-century Supreme Court. Realist jurisprudential sentiments - primarily as articulated in terms of the so-called indeterminacy critique - continue to bear an influence on late twentieth-century critical legal thought.*

1 Scandinavian legal realism

Within twentieth-century legal thought, the term 'legal realism' is used very broadly to describe two branches of jurisprudence which stand opposed to legal idealism (see Legal idealism §1). These two branches of jurisprudence - Scandinavian and US legal realism - are not connected, nor do they conceive of idealism in the same fashion. In the Scandinavian countries, legal realism represents a reaction against the influence of German idealist metaphysics on jurisprudential thought. In the USA, realism constitutes a critique of idealism implicit in late nineteenth- and early twentieth-century common law teaching and doctrine.

The Scandinavian version of realist jurisprudence is both inspired and epitomized by Axel Hägerström's writings on the philosophy of law and morals (Hägerström (1953). Legal rights and duties, he contends, cannot be identified as factually existent and therefore cannot be considered 'real'. Despite their unreality, however, rights and duties clearly do exist in some sense. The question which Hägerström thus poses is that of how, if these entities do not exist empirically in the physical world, they can be known and their contents ascertained. His answer to this question is that rights and duties constitute personal feelings of entitlement and obligation (see Emotivism). There exist 'feelings of duty in regard to the restrictions which affect oneself', just as there exist 'feelings of power in regard to the acquisition of advantages… which are regarded as rights'. Thus it is that 'an individual who infringes the right of another lays himself open to reactions from the latter which gain a special strength through feelings of power of a special kind, which are connected with the idea of rights' (Hägerström 1953: 15).

Whereas Hägerström acknowledges that the concepts of right and duty possess psychological force (even if they cannot be empirically ascertained), his friend Vilhelm Lundstedt went so far as to argue that rights and duties are merely chimeras, discussion of which is inappropriate within a science of law (Lundstedt 1957). Indeed, Lundstedt would happily have seen analysis of rights and duties banished from jurisprudence. Other writers within the Scandinavian realist tradition none the less recognized that the concepts of right and duty possess considerable intuitive appeal. While these concepts may be essentially hollow, Alf Ross noted, the very fact that legal language is so dependent on the words 'right' and 'duty' suggests that legal statements about rights and duties - as opposed to rights and duties themselves - deserve serious philosophical attention (Ross 1958 §35). Karl Olivecrona offered a still stronger argument in favour of the study of rights and duties. '[T]he proposition that there is a law without rights and duties', he observed, 'seems to be contradictory since it belongs to the very essence of the law that it regulates people's rights and duties' (Olivecrona 1971: 184). Furthermore, even if the argument that rights and duties are chimeras was correct, 'the practical conclusion should not be to throw the terms overboard but to study their functions' (Olivecrona 1971: 178).

2 US legal realism

In the context of US jurisprudence, 'legal realism' is a remarkably ambiguous concept. At the beginning of the 1930s - responding to Roscoe Pound's cursory dismissal of 'the realists' (Pound named no one specifically) as a group of legal philosophers who exaggerated the jurisprudential significance of social science while underestimating the importance of legal rules, doctrines and principles (Pound 1931) - Karl Llewellyn endeavoured to put flesh on the bones of realist jurisprudence by identifying a 'sample' of realist legal philosophers (see Pound, R.). Since then, various excellent studies have been produced, focusing on, among other

things, the political (Purcell 1969) and social-scientific (Schlegel 1979) dimensions of realist legal thought, as well as on particular realist figures (Twining 1985).

US legal realism might be described very basically as a mood of discontentment with the idealism implicit in late nineteenth- and early twentieth-century US common law thought. This discontentment was directed towards two distinct juridical tendencies.

First, legal realism represented an expression of dissatisfaction with Langdellian idealism. The appointment of Christopher Columbus Langdell as Dean of the Harvard Law School in 1870 signalled the emergence of modern legal education in the USA (LaPiana 1994). Langdell's primary pedagogic initiative was to dispense with the traditional lecture method of teaching and put in its place the so-called 'case method' of instruction. The case method is a style of teaching which emphasizes the acquisition of knowledge through Socratic dialogue. The student subjected to this method is required to read judicial decisions in advance of class so as to be prepared to answer questions about their content and their reasoning. By teaching their subject in this fashion, Langdell and his followers were able to promote a highly abstract, idealistic - what they considered to be a scientific - image of the common law as a set of logically interconnected core doctrines and principles.

Legal realists tended to object to the scientific pretensions of Langdellianism. The idea that teaching law by the case method was tantamount to teaching law as a science was considered by various realists to constitute a form of erroneous idealism. In short, Langdellianism depicted law as mere logic rather than as experience, as something to be found in books rather than in society. Certain legal realists believed that law could be conceived as a science, but not in the Langdellian sense. For these realists, social science was the key to depicting reality.

Different legal realists took the concept of social science to denote different things. Predictivism and empiricism feature prominently as social-scientific themes in realist jurisprudence. Through 'fact research', certain realists believed, it may be possible to assess the quality of particular laws as instruments of social control and to predict the likelihood of those laws being infringed or ignored in the future (see Moore and Callahan 1943). It may well be that certain laws are difficult to enforce, or, when successfully enforced, entail an inordinately weak sanction. Someone may decide to break a particular law if they believe that their chances of being caught in breach of that law are minimal, or if the profit that they will acquire by breaking that law outweighs the fine which they might incur. Legal realists, in presenting this argument in social-scientific terms, were echoing the theory of Oliver Wendell Holmes of the 'bad man' (Holmes 1897). Other realists, in resorting to the social sciences, attempted to move realist legal thought beyond the shadow of Holmes. In this context, the work of Jerome Frank is exemplary.

Second, just as US legal realism may be understood as a reaction against Langdellian idealism, so too it may be understood as a reaction against the idealism embodied in the economic outlook of the late nineteenth- and early twentieth-century US Supreme Court. In a number of decisions - *Lochner* v. *New York* ([1905] 198 US 45) and *Coppage* v. *Kansas* ([1915] 236 US 1) are the most illustrious - the Court basically combined *laissez-faire* with social Darwinism. All citizens, the Court argued, possess an equal right to compete in the marketplace. This does not mean, however, that all citizens in fact possess an equal capacity to do so. Some will compete more, some more successfully than others, so that the strongest economic actors will prosper at the cost of the economically weak. In other words, an inevitable corollary of a formal equality of bargaining rights is a real inequality of bargaining power. Guided by this philosophy, the Supreme Court felt justified in constitutionally invalidating state legislation that attempted to redress inequalities of bargaining power. Freedom of contract was thus constitutionally enshrined.

For certain legal realists, the constitutional philosophy of the Supreme Court served simply to highlight the impossibility of real freedom of contract. Owing to the fact that there exists inequality of bargaining power among economic agents, they argued, markets must be essentially coercive rather than free. According to Robert Hale, one's capacity to make choices in the marketplace is determined by the extent of one's bargaining power (Hale 1923). Morris Cohen expressed the point pithily: 'The freedom to make a million dollars is not worth a cent to one who is out of work. Nor is the freedom to starve, or to work for wages less than the minimum of subsistence, one that any rational being can prize - whatever learned courts may say to the contrary' (Cohen 1933: 560). While the USA was suffering the effects of the Great Depression, the Supreme Court continued to invalidate economic regulatory statutes on the ground that they offended against the constitutional sanctity of free exchange.

This ‘economic’ strand of realist legal thought has sometimes been interpreted as an outright rejection of the possibility of economic freedom. But realists such as Hale and Cohen were not denying the possibility of economic freedom *per se*. They were arguing, rather, that such freedom cannot flourish in an unregulated market. Hale in particular believed that regulation may serve to facilitate rather than to inhibit market freedom. His argument was by no means as radical as has often been assumed (as, for example, by Kennedy 1993), who interprets the argument as a rejection of the possibility of market freedom).

3 The legacy of legal realism and the problem of indeterminacy

The general assumption that US legal realism was somehow radical - that it was the rebellious offspring of the modern US law school - ought to be questioned. Certainly many legal realists took issue with the Langdellian idealist belief that rules are generally certain and capable of mechanical application to legal disputes. What we do not find in the literature of US legal realism, however, is a celebration of legal indeterminacy (see Critical Legal Studies §2). One of the classic realist insights - that judges may sometimes ignore rules and principles and decide cases instead on the basis of personal intuition or ‘hunch’ (Hutcheson 1929) - was regarded by many realists as a cause for lament rather than celebration. Very simply, indeterminacy in adjudication was regarded as a problem.

It was a problem, furthermore, to which realism offered no persuasive answer. Some legal realists believed that remedying the problem of indeterminacy in adjudication demanded the development of a new kind of legal certainty: Holmesian, predictive certainty as opposed to Langdellian, deductive certainty. This line of argument finds its most complete expression in Llewellyn’s masterful study of the ‘steadying factors’ in the common law tradition (Llewellyn 1960). Still other realists, however, insisted that the belief that there exist determinate patterns of regularity in adjudication was no less ill-founded than Langdellian legal science itself (see Frank 1930). These realists - figures such as Jerome Frank, Wesley Sturges and Thurman Arnold - identified, but did not know what to do about, the existence of indeterminacy in adjudication. Thus it was that the problem of indeterminacy revealed the fundamental limitation of realist jurisprudence in the USA. Harold Berman recounts an illustrative story in this context concerning Thurman Arnold delivering a seminar at the Yale Law School in 1947. In this seminar, Arnold was apparently spinning the familiar realist line about how instinct rather than rule-following is the dominant feature of adjudication when he was interrupted and asked if that is how he had decided cases while a judge on the Columbia District Court of Appeals in the early 1940s. Berman takes up the story:

> Arnold paused before answering; one had the impression that he was transforming himself from Mr Hyde to Dr Jekyll as the professor in him yielded to the judge. He replied, ‘Well, we can sit here in the classroom and dissect the conduct of judges, but when you put on those black robes and you sit on a raised platform, and you are addressed as "Your Honor", you *have* to believe that you are acting according to some objective standard.’
>
> (Berman 1974: 30)

Arnold is certain that there is something more to the adjudicative process than what lawyers have traditionally identified. But he is unable to pinpoint what that ‘something more’ might be. Other realists, in confronting this problem, placed their faith in the notion of expertise: indeterminacy need not be feared, they argued, so long as legal officials are experts in what they are entrusted to do (see Frank 1949). Many legal philosophers who searched for safeguards to US democracy in the face of growing tyranny abroad were far from appeased by this argument (Duxbury 1992; Purcell 1969). Yet this is about as near as US legal realism came to offering an original theory of adjudication. One of the primary legacies of realism rests in the fact that it impressed upon US academic lawyers the importance of developing such a theory. It is to this task that US jurisprudence in the post-realist era has been overwhelmingly devoted.

Legal reasoning and interpretation

Legal reasoning is the process of devising, reflecting on, or giving reasons for legal acts and decisions or justifications for speculative opinions about the meaning of law and its relevance to action. Many contemporary writers, such as Aulis Aarnio (1987), Robert Alexy (1988), Manuel Atienza (1991) and Aleksander Peczenik (1989), propound the view that legal reasoning is a particular instance of general practical reasoning. They suppose, that is to say, that reasoning can link up with action, guiding one what to do, or showing whether or not there are good reasons for a proposed course of action or for something already done. They suppose also that in law reason links up to legal decisions in this way. Both suppositions are well founded. Law regulates what to do and how to respond to what has been done, doing so within an institutional framework of legislatures, lawcourts, enforcement agencies and the like. It is a feature of legal institutions that they are expected to have, and usually do give, good reasons for what they do, and to do this in public. Legal reasoning is therefore not only a special case of practical reasoning, but a specially public one.

Rationality in action has at least two requirements: first, attention to facts, to the true state of affairs in relation to which one acts; second, attention to reasons for action relevant to the facts ascertained. The former aspect concerns reasoning about evidence; the latter, reasoning about rules or norms as reasons for action. In law, such rules and other norms have an institutional character. But how are these applied - by some kind of deductive reasoning, or nondeductively? Behind the rules of the law, there presumably lie other reasons, reasons for having these rules. What kind of reasons are these, developed through what modes of discourse? A discourse of principles, perhaps - but then how do reasons of principle themselves differ from rules? Reasoning from either rules or principles must always involve some process of interpretation, so how does interpretive reasoning enter into the practical reason of law? Answering such questions is the business of a theory of legal reasoning. Legal reasoning is to be understood as a form of practical reasoning concerning these very issues.

1 Legal reasoning and questions of fact

A general requirement of sound practical reasoning is that there be due consideration of the facts relevant to a decision. A decision must be appropriate or fitting to its context. Doubts about and evidence concerning questions or opinions of fact have to be weighed and conclusions reached about the facts at issue. In law, decisions have to be made in relation to procedurally formalized claims or accusations, usually concerning particular past events. Claims and accusations have to be proved by admissible evidence. But what constitutes proof? The narrative coherence of an account of events connected to reliable present testimony seems to be an essential test, but proof of this sort can never amount to absolute certainty. Hence all legal proceedings have to address some standard of proof: ‘proof beyond reasonable doubt’, or ‘proof on the balance of probabilities’, or that proof which is found ‘convincing’ by the trier of fact. The burden of proof has to be determined.

So far as proof demands a judgment of probabilities, it is a question of whether or how far probability should be interpreted according to a Pascalian or mathematical/statistical model, or should be interpreted as a form of ‘Baconian’ probability, as argued by Jonathan Cohen (1977). It is submitted that the overall probability of a case should be interpreted in Cohen’s terms, but with due allowance made for the legitimacy of statistical methods when forensic-scientific analysis can cast light on some key evidential fact or facts (see Legal evidence and inference).

Important though careful factual reasoning is in processes of decision-making, on its own it is insufficient to bring practical reasoning to any conclusion. Some transformation of factual reasoning into normative conclusion is called for. That is, there has to be some further reason why to act or decide in a certain way given that the situation is held to be such-and-such. Such reasons must be right-making, showing the act or decision as right for those facts.

2 Rules as reasons: deductively applied?

What kind of such reasons are there? One possible answer is ‘rules’. If there were a rule that act A ought to be performed in circumstances C, then, if it were established that C, the appropriate act in the circumstances would be A. It seems straightforward to turn this line of reasoning around and express it as a *modus ponens* hypothetical

argument. ‘If ever C, then A is right; C, so in this case A is right.’ This assimilates practical syllogisms to ordinary deductive arguments, save that the major premise is a normative rather than a factual generalization. But the view that practical reasoning can be straightforwardly assimilated to ordinary deductive reasoning is extremely controversial. And lawyers have frequently warned against the confusion of law with (deductive) logic.

There are difficulties. First, what is presupposed in appealing to a rule in such a setting? By virtue of what could a governing rule be said to exist? Two possibilities may be suggested. The first is the establishment of a rule by some form of authority, for example as a rule of a game, by the governing body of the sport in question; or as a rule of a school or university, by its governing body; or, finally, a rule of a legal system, established by the legislature. For a rule to count as a reason in this setting, it has to be presupposed that it is right to defer to that authority, and the problem of justification thus seems to lead out beyond any established rule or rules. We therefore need to look at the second possibility: that there is some reason to follow the rule other than the fact of its being an authoritatively established rule in some rule-system. What could such reason be?

3 Grounds for rules: appropriateness and rhetorical argument

At this point, there seem to be three possibilities: that the rule is endorsed as appropriate in itself; that it derives from a principle which is appropriate in itself; or that it is a rule justified by the value of its consequences, that is, by the consequences of following it as a rule - but in that case, some principle confirming the positive value of such consequences is presupposed, and the appropriateness of the principle is also presupposed. Returning to the question of authority, it can now also be said that the reason for accepting authority must evidently be the appropriateness of following the rules and/or principles that constitute the authority.

We are forced into considering the notion of that which is ‘appropriate’. One account could be in terms of some faculty of direct apprehension or intuition (see Intuitionism in ethics), whereby we are able immediately to recognize such appropriateness or other moral qualities. But if such an appeal to intuition is sound, why is there need for appeal to a rule at all? If we are capable of intuitively grasping the appropriateness of a rule in itself, or of the following of a rule established by an authority whose appropriateness is intuitively clear, can we not then simply apply that faculty of intuition directly to the case itself? May it not be that the appropriateness of the act to its circumstances is itself the justifying reason for the act? M.J. Detmold (1984) has argued that if one were incapable of seeing the force of such reasoning from the appropriateness of a particular act to its particular circumstances, one would be equally incapable of seeing the appropriateness of a rule, and hence incapable of arguing from rules. The foundation of legal (and moral) reasoning in this view lies in our capacity to judge what is right in individual cases, including a capacity to perceive when it is right to treat a particular case as a case covered by a rule, and decide accordingly.

Whatever may be the ultimate inevitability of some appeal to intuition, it does seem that recourse to this ‘black box’ ought to be deferred as long as possible in the analysis of any process of reasoning. Especially in practical reasoning, and most spectacularly in the case of legal reasoning, there are possibilities of argumentation, reasoning and discussion of a quite public kind over the issue of what is here called ‘appropriateness’.

Wherever there is a process of public argumentation, there is rhetoric. The modern rediscovery of rhetoric as a discipline owes much to reflection on legal reasoning. Theodor Viehweg, drawing on Aristotle, has pointed out the significance of *topoi*, or ‘commonplaces’, in rhetorical arguments. An argument for a particular rule or proposition can be supported by reference to some accepted *topos*, and arguments progress by working towards, or from, such commonplace positions. In law, there are maxims and long-standing principles and presumptions, such as ‘no one can give a better right than they have themselves’ or ‘a later law derogates from an earlier one’ and suchlike. Likewise, there are well-established argument forms such as *argumentum a fortiori*, *argumentum a maiori ad minus*, *argumentum per analogiam* and the like. An argument in such a recognized form starting from or working towards a recognized *topos* is well calculated to be persuasive in its given context.

In a not dissimilar way, Josef Esser (1970) drew attention to the importance of *Vorverständnisse*, ‘pre-understandings’, the taken-for-granted assumptions that enter any judgment of what is acceptable in the setting of legal argumentation - and in the preference of one method of arguing over another in a particular case. Once premises and mode of argument are settled, it is simple to produce an argument that satisfactorily justifies the conclusion reached. But the problem then becomes one about the reasonable choice of premises and method, so

there must be inquiry into pre-understandings. Aulis Aarnio (1987) has suggested that in the end these may simply have to be assessed as the ‘form of life’ that they constitute.

Chaim Perelman’s *La Nouvelle Rhétorique* (1958) emphasizes that arguments are necessarily addressed to an audience, and that persuasiveness is audience-relative. This is especially obvious in legal practice, where trained advocates put cases before courts as persuasively as possible, and judges decide after weighing their rival arguments on points of law. But persuasiveness is not the same as soundness. The issue for a theory of reasoning-as-justification is not what argument actually persuades a particular judge or jury, but what ought to convince any rational decision-maker. In this connection, Perelman postulates a ‘universal audience’ as providing the ultimate test; whatever argument would convince an audience of all intelligent and interested beings is a sound one. At the same time, Stephen Toulmin (1964) proposed a reinterpretation of traditional logic as regulating argumentative moves, and supplying warrants for moves from premises to conclusions, rather than as capturing timeless truths about rational thought.

The weakness of the rhetorical turn in analysis of practical reasoning is to reduce appropriateness to persuasiveness. Appeals to the universal audience or to any actual consensus seem unhelpful, since apparently we work out what would persuade the universal audience by reference to what is sound, not vice versa. Yet again, certain ‘critical’ approaches to legal thought urge that the claim to an objective soundness of legal reasons is the grandest rhetorical turn of all, enabling ideology or class interest to be misrepresented as some kind of ultimately sound reason or sound reasoning (see Critical Legal Studies; Legal discourse).

4 Procedural aspects: rational discourse

A procedural approach to practical reasoning may provide a solution to the problems posed by theorists of rhetoric and their critics. The question is what constraints upon reasoning it is rational to accept in order to come to acceptable conclusions. Here, the rhetoricians’ emphasis on the interpersonal context of argumentation is reiterated. In its light, the concept of universality has two uses: first, in stipulating universalizability of reasons - for the present instantiation of C to count as a reason now for doing A, it would have to be acceptable to hold A appropriate whenever an instance of C occurs; second, in testing the acceptability of any such reason - the universalized reason has to be acceptable to any interested party, and be challengeable by reference to anyone’s feelings, interests or opinions; but any opinion or feeling or interest is challengeable as to its relevancy, and so on. As Jürgen Habermas (§4) and followers like Robert Alexy (1988) argue, it may be possible to test practical propositions by reference, at least in principle, to the interests and views of the totality of persons in any way affected by or concerned with them. Habermas proposes a test by reference to dialogue in an ‘ideal speech situation’, envisaged as one in which all forms of coercion or interpersonal power or domination are put aside for the purposes of conducting (or imagining the conduct of) interpersonal discourse (see Communicative rationality §1). Analysis of the necessary constraints on such a discourse yields a procedural approach to testing the kinds of principles that rational discourse-partners could accept, acknowledging the types of desires and interests they actually have. Important in this is the idea that accepted principles or *topoi* should be subject to challenge, but are considered acceptable until successfully challenged, for example, on the ground that they cannot pass the test of universalizability or on the ground that they owe their origins to inequalities of power irrelevant as reasons in the ideal speech situation.

It is doubtful whether this procedural approach wholly disposes of recourse to intuition. It remains a question why some principles of argument must be accepted as ‘rational’ after all. But the merit of the approach is that it both postpones and narrows appeals to intuition, and scrutinizes the appropriateness of practical principles and rules in the light of acknowledged constraints of rational discourse. Commonplace principles are still needed as starting points, but they are challengeable within the argumentation. One requirement of rationality is that principles and rules be shown both to be mutually consistent and also to have overall coherence, working in priority rankings and weighing procedures to resolve *prima facie* conflicts.

This discourse-theoretical evolution of the rhetorical approach largely substitutes for without finally supplanting intuition in accounting for the idea of the appropriateness or rightness of a rule as a reason for action, and the appropriateness of other reasons in justifying either the content of a rule or the authoritative status ascribed to it. Insistence on universality in both the senses deployed here is also of value in blocking appeal to some particular ineffable intuition as a sufficient justifying reason for a particular decision in a particular case. The reason must at

least be statable as ‘whenever C, then A’, and some reason given for that, including a testing of it for consistency and coherence with other accepted rules, principles and unchallenged commonplaces.

5 Rules again: exclusionary reasons

Hitherto, it has been taken for granted that rules can be justifying reasons for actions. Now we are in a position to pose the question: ‘Why rules?’ Why should we have started from thinking of rules as reasons for decisions, rather than principles of rational decision-making such as might emerge from a procedurally articulated practical rationality? Rules are one type of normative entity. Their distinctiveness lies in what has been called their character as ‘exclusionary reasons’ (Raz (1975) or ‘entrenched generalisations’ (Schauer 1991). These terms draw attention to the special way one appeals to a rule in reasoning, namely as a factor that excludes consideration of otherwise relevant features of the situation. Appealing to a rule is appealing to an ‘exclusionary reason’.

Consider this: as a matter of principle, one ought to drive with due regard for the safety of others; it is a rule that one stop at red traffic lights. To respect the rule as a rule means abstaining from deliberation in particular cases whether due regard for the safety of others requires stopping at a given red light on a given occasion. The rule is a reason to stop and a reason not to reflect further on the wisdom of stopping (which does not mean that there may not be emergencies that cancel the rule). One can, by contrast, respect the principle as a principle while allowing that in a given context it can be outweighed by considerations arising from rival principles.

How then can rules belong in a theory of practical reason? How can reason mandate the exclusion of reasons? A common answer is that human coordination problems may give special utility to fixed rules for application by all parties whose actions have to be coordinated. In any interpersonal context in which pure principled reasoning guided by procedures for rational practical discourse would or could lead to conflict of soundly justified opinions (and actions) on points of conduct in shared social space, recourse to a rule is the best way to achieve the least unreasonable results on the whole, even though there are occasions when application of the rule yields non-optimal results. (Traffic-light rules exemplify this clearly, and indeed in Britain the Highway Code largely comprises rules for solving coordination problems in areas where reliance on pure principle would be obviously hazardous.)

Pure recourse to unaided practical reason without recourse to rules and authority would not yield satisfactory grounds for interpersonal decision where coordination is called for. It is therefore reasonable for humans to have or to establish authorities exercising powers of rule-making and of rule-applying. That is, it is reasonable to have law (in various forms), and reasonable that law comprise in large measure relatively detailed rules established through legislation (and possibly through precedent also). This is what establishes the special sphere of legal reasoning as a separate branch of general practical reasoning, with appropriate special principles, rules and forms of argument. Rules duly established through law are appropriate grounds for decision-making both by citizens in relation to their own conduct and by judges and other officials in decision-making in cases involving citizen-citizen or citizen-state conflict or dispute.

Earlier, it was suggested that reasoning where rules are applied is essentially deductive. To show that a rule is being applied, one states the rule ‘if C then A’, and states one’s finding that ‘C’ is satisfied in this case. ‘A’ can then be stated to follow as the appropriate action in the circumstances that obtain. In very straightforward cases, this indeed seems to be a complete account. But cases are frequently harder, in obvious ways. First comes the problem of possible conflicting interpretations of the rule. What does the rule properly mean? How should it be interpreted for this case? Second comes the problem known to lawyers as that of ‘qualification’ or ‘characterization’ of the facts and circumstances. For example, suppose there is an acknowledged rule not to commit adultery. If a married woman wishes to have a child, but cannot become pregnant by her husband, would it count as adultery if she participated in artificial insemination by donor (AID)? Would it make a difference if the donor were unknown or known? Or if her husband objected or consented? How should we qualify these facts having regard to the assumed rule? If a wife is pregnant through AID and if adultery is a ground for divorce, is her husband entitled to a divorce on the ground of her adultery? Whenever a rule is in view, it is crucial whether or not given facts can be legitimately so characterized as to fit the rule, or be distinguished from it. A similar question can be posed in a broader way, asking which of a range of possible interpretations of the general rule should prevail, given the wording of the rule, the general legal context of its enactment, and any values at stake in its implementation.

6 Legal reasoning beyond deduction

Even in cases where rules are *prima facie* applicable in a direct way, there can be problems of qualification and of interpretation, and a part of the rhetorical training of lawyers develops their attentiveness to such problems whenever helpful to the case they must advocate. Moreover, there may be many situations which, although not covered directly and unambiguously by an established rule, do nevertheless bear some closer or remoter analogy to the situation the rule expressly covers, and to which acceptable arguments of principle favour a resolution founded in this analogy. Decisions taken to deal with such problems or to uphold or reject the analogy may themselves constitute precedents offering grounds for future resolution of like problems. There is an obvious ground of justice for paying regard to such precedents in later cases, and the more the regard that is in fact paid on that ground, the stronger becomes the justice of holding to precedent, in view of expectations founded on the practice of following them.

This shows why the (essentially deductive) rule-application paradigm of argumentation, justifying a decision simply as an application of a rule to a particular case considered to be an uncomplicated instance of the generic case stipulated in the rule, is rarely if ever sufficient in itself fully to justify a decision. There have to be reasons for a favoured interpretation of the rule, reasons for a favoured qualification of a fact-situation, reasons in favour of pursuing or rejecting an analogy. Theories of legal reasoning have tried to elucidate its character in these areas that lie outside the simple deductive model.

Some of its features derive directly from constraints of practical reason itself. Thus reasons for interpretations or classifications have to be universalizable, as must be grounds for decision supported by analogy. There must be some explicit or implicit ‘holding’ or ‘ruling’ or ‘maxim’ of the case that accounts for the decision favoured, and that must be universalizable if not explicitly stated in universalistic terms: ‘given that adultery requires an actual act of sexual intercourse, pregnancy by AID is not to be considered proof of adultery’ would be an example. Any claim to justification through such a holding entails a commitment to its universal applicability - to every instance of AID complained of as adulterous *per se*, not only this one. This pushes the problem back a stage, but does not solve it, for the question at once arises how to justify the ruling or holding conceived in universalistic terms. There are but two possibilities. There must be deontological or teleological reasons in play (‘rightness reasons’ or ‘goal reasons’, according to R.S. Summers 1978). Either it must be shown to be in principle right to restrict ‘adultery’ in this way, or it must be shown to be preferable to the alternative upon consequentialist grounds.

Reasons of principle have a dual aspect here. On the one hand, since the context of decision is a legal one, and since the concepts at issue are legal, bedded in fundamental doctrines of family law, there is a necessary interpretive element: one has to establish a good account of the values that underpin the particular view of marital fidelity (or whatever, depending on the area of law in view) enshrined in the whole relevant body of law. On the other hand, there is the test of general practical reasonableness (here interpreted in the procedural model of practical rationality, though others are available). Teleological or consequentialist reasoning places the stress on the legal acceptability or unacceptability of the state of affairs represented by one or another of the rulings that come under view. Evaluation of the ‘acceptable’ or ‘unacceptable’ in the legal setting has regard to the legal-institutional framework, and to values that make sense in this framework. So the difference between deontological and teleological in this setting may be more one of presentation than one of fundamentals. In either event, an effort is made to interpret the broad sweep of the law in terms of its point or its underlying value or values, and on this account Ronald Dworkin 1986) has characterized ‘law’ itself as an essentially ‘interpretive concept’.

However that may be, there is another aspect of interpretation rather narrower and more exact in its reference. As noted, there are frequently issues of the interpretation properly to be put upon the terms and provisions of enacted law. While it is undoubtedly the case that this proceeds under the above-noted constraint of universalizability, nevertheless reasons for interpretations are also often strongly (and legitimately) relativized to the particular statute, its particular wording, its particular legal context, and (sometimes) particular purposes imputed to it either on objective grounds or having regard to evidence of the particular aims of the legislature that enacted it. Universalizably justifiable practices of interpretation require attention to the integrity of linguistic communication through the medium of enacted law, to the overall coherence of statute law, both internally to the particular statute and externally in testing its consistency and fit with the rest of the legal system in which it takes its place. A

similar principle in favour of the overall coherence of law is also in play where argument by analogy, in particular argument by analogy with settled precedents, is advanced in justification of decisions. Here too, the case for or against extending by analogy from the law as already settled to some novel formulation is subject to testing and critique both deontologically and teleologically. Interpretation of statutes and of precedents, and arguments by analogy in both contexts, have accordingly a particular part to play in legal reasoning.

Some commentators treat this as too restricted a view of the place of inductive or analogical reasoning. E.H. Levi's classic *An Introduction to Legal Reasoning* (1948) portrayed analogical development as the essential moving force of the common law, and its most characteristic style of reasoning. More recently, Steven J. Burton (1985) and Bernard S. Jackson (1988) have argued respectively that analogical reasoning has either coequal status with the deductive rule-based paradigm suggested above or (in Jackson's case) clear primacy over it, on the ground that all our reasoning has most fundamentally a narrative structure, such that the human capacity for pattern-matching among narratives accounts both for the human skill of analogical reasoning and the human capacity to make sense of rules. The present attempt to postpone recourse to and narrow the scope of appeals to intuition applies also to this essentially intuitionistic conception of pattern-matching; but it is not hostile to the claim that analogical reasoning is omnipresent in the adjustment of legal norms to social values. It is submitted that although argument by analogy has indeed a special role in the development of law and in processes of rational 'discovery' in developing new legal doctrine, nevertheless it has to be viewed as one part of a wider conception of legal reasoning as a special case of practical reasoning.

Legalist philosophy, Chinese

Legalist philosophy constitutes one of the three dominant streams of Chinese philosophy along with Confucian and Daoist philosophies. It aims to establish objective, impartial and impersonal standards for human conduct. It sets forth prescriptive models using such metaphors as the builder's plumb line and carpenter's L-square. 'Modelling after' implies reshaping and remoulding of human behaviour, not by moral suasion but by the application of fa, *a term designating both prescriptive standards and promulgated penal law, designed to achieve public interest.*

*The idea of remoulding by punishment and reward is predicated on the Legalist conception of human nature. Innately self-interested human nature underlies human behaviour of liking reward and disliking punishment. Hence, penal law is both natural and an objective prescriptive technique for behavioural control that seeks to harmonize both the individual and the public interest. Penal law is efficacious in so far as it is issued from an authoritative power (*shi*) based on impersonal, institutionalized position of rulership and borne up, however tacitly, by the support of the people.* Shi *cannot govern effectively, Legalists argue, without the organizational power of bureaucracy under the centralized control of the ruler. For the ruler, controlling bureaucracy means mastering the technique (*shu*) of comparing 'word' (*ming*) and actual 'performance' (*xing*), not only through objective mechanisms of empirical verification but also by means of 'the two handles' of power over life and death. Hence, the technique holds bureaucracy accountable.*

The Legalist philosophy of governing by fa, shi *and* shu *was in effect a new model for sociopolitical reorganization. It became increasingly popular during the Warring States period, a time of incessant political struggle and of irreversible systemic disintegration of the Zhou feudal order. Legalists called for a radical systemic transformation through this new model in the name of historical relativism: 'There are as many situations as there are generations… and situations change, so the measures change' (*Han Feizi 49*).*

Historical relativism notwithstanding, Legalist philosophy envisages a 'natural' and 'automatic' polity that, once established, accords with dao *(that is, the way the natural world operates spontaneously). The ruler practices 'non-action', 'emptiness' and 'quiescence' so as to embody* dao, *and thereby personifies objective, impersonal standards over subjective, personal preferences. Once this 'natural' polity is established, the ruler does not act while his subordinates act according to* xingming *accountability as noted above. The ruler does not act as the centre point of the scale does not move, and yet he knows which side is heavy and which side light. In the end, the ruler does not act so that he can act, that is, so he can employ 'the two handles' to control his subordinates. This seemingly 'natural' and 'automatic' polity still requires a 'sage' ruler extraordinarily adept at covert statecraft. Only such a 'sage' ruler can hope to achieve order, wealth and power for himself and for his people.*

1 *Fa* as prescriptive standard and penal law

The term *fa* means not only 'law' but also means 'model', 'standard' or 'method'; therefore, it needs to be understood contextually (see Fa; Law and ritual in Chinese philosophy). Hence, the conventional translation of *fajia* (school) as the 'Legalist School of Thought' is misleading in that it overemphasizes the term 'law'. Moreover, the term *fajia* is retrospectively attributed by the Han doxographers, particularly Sima Tan (d. 110 BC), to a group of thinkers and statesmen who shared a sufficient measure of common philosophy of governing but certainly did not constitute a 'school' in the sense of the Confucian and Mohist schools. They did not have master or canonical texts and they did not live a communal life.

The third of the 'Seven Standards' of *Guanzi*, attributed to the proto-Legalist Guan Zhong (d. 645 BC), defines *fa* as 'standard' and refers to the carpenter's ink and line, compasses and L-square, the scale and the volume measures, metaphors that suggest mechanical precision and impartiality. The 'Seven Standards' are set forth as the knowledge required by the ruler for effective government. The fifth is specifically designed for transforming or reforming the people: 'Giving to or taking from, endangering or securing, benefiting or harming…killing or giving life, are called "incentives" and "deterrents"' (*Guanzi* 35). The idea of 'standard' is succinctly stated by the pre-eminent Legalist Han Feizi: 'The [*fa*] no more makes exception for men of high station than the plumb line bends to accommodate a crooked place in the wood' (*Han Feizi* 6).

Fa, understood as 'model' or 'standard' of behavioural pattern, is not exclusively Legalist; it is clearly present in

Mozi (canons A70, A94) and *Mencius* (4B1). These texts placed primary emphasis on 'government by virtuous example' and held that even the benevolent heart of a virtuous ruler would not achieve good government without the aid of the carpenter's compass and L-square. While the punitive connotation of the word *fa* became more pronounced in the Warring States period, for Legalists, *fa* continued to mean a whole network of 'standardized' patterns of behaviour. Thus to the Legalist Shang Yang (d. 338 BC), 'changing *fa*' meant a call for a new 'model' of sociopolitical institutions with corollary implications for behavioural change according to the Legalist standards.

Fa is most commonly understood as penal law. Contrary to conventional wisdom, however, the Legalists did not invent 'severe punishments and strict laws'. In the proto-Confucian canonical texts such as the *Shujing (Book of Documents)*, King Wu, the founder of the Zhou dynasty (*c*.1040-56 BC), and his brother Duke of Zhou emphasized the rational role of coercive force for a righteous cause. The Duke of Zhou advises Prince Kang to administer severe punishments according to the laws and not to bend them to agree with his 'inclinations'. Those who commit '[serious] crimes…are greatly abhorred, and how much more detestable are the unfilial and unbrotherly.… You must punish them severely' (*Shujing* IX). As Schwartz (1985) observes, the enduring legacy of meting out 'the most horrendous penal sanctions' for violation of family morality, which was supposedly held together by kinship affection, was legitimized by canonical texts. The Legalist doctrine of 'severe punishments and strict laws' likewise harks back to canonical texts. In these texts, however, there exists a judicious balance between civil and coercive administration, whereas Shang Yang and Han Feizi stress Draconian penal codes under the compelling exigencies of Warring States power politics.

2 *Fa* and human nature

How do Legalists justify their claim that *fa* is both 'objective' and 'natural'? How is *fa* related to their conception of human nature? In fact, the Legalist approach to human nature is sociological. Of the goodness and badness of human nature, Guanzi observes: 'It is not a matter of man's nature, but of poverty' *Guanzi* 35). Han Feizi speaks of changing values and behavioural patterns when the population increases in geometric progression while provision for it grows in only arithmetic progression (*Han Feizi* 48). As a consequence, people compete so fiercely for survival that disorder becomes rampant even if rewards are doubled and punishments multiplied. Han Feizi contends: 'The generosity with resources in ancient times was not benevolence, it was because resources were ample; the competition and robbery is not dishonesty, it is because resources are sparse.' Thus the Legalist philosophy of human nature is significantly different from that of Hobbes.

Legalists argued moreover that self-interestedness does not necessarily imply harming others. Han Feizi observed that the physician sucks patients' wounds and holds their blood in his mouth not because he loves them but because he expects profit from them. It does not mean the cartwright is 'benevolent' for wishing people to be wealthy enough to buy his carriages, nor does it mean the carpenter is 'cruel' in desiring to sell as many coffins as he can. Self-interestedness is clearly differentiated from selfishness, for it is considered a natural human condition that is ethically neutral.

People are more powerfully motivated by self-interest than the sentiments of concern for each other. This is also recognized in Western philosophy. In his *The Theory of Moral Sentiments*, Adam Smith says: 'Every man is, no doubt, by nature, first and principally recommended to his own care.' Thus, when one hears of millions of Chinese being swallowed up by a stunning and hellish earthquake, one might momentarily feel badly but would then go about one's business and sleep soundly. 'If he was to lose his little finger tomorrow, [however], he would not sleep tonight' (Smith 1759 [1976]: III.3.4). Legalists assert that *fa* must accord with human feelings of self-interest for it to be 'objective' and 'natural'. Because human feelings have likes and dislikes, reward and punishment can be effectively applied, and when prohibitions and order prevail, good government can be achieved. The critical function of *fa* is to effectively regulate and channel the general tendency of human nature toward personal welfare in order to realize the principal goals of good government.

Given the natural tendency to be self-interested, how many people would spontaneously harmonize their concern for private welfare with public interest? How is the convergence of private and public interest to be effected? Han Feizi replies that one can neither count on arrows that are straight of themselves nor count on pieces of wood that are round of themselves in a thousand generations, and 'yet how is it that people of every generation ride carts and shoot birds? It is because the tools for straightening and bending are used…' (*Han Feizi* 50). The 'tools' are, of

course, *fa*. *Fa* to one who governs is like the carpenter's L-square and compass - the objective, impersonal and prescriptive instruments for 'straightening and bending' - in short, for remoulding and channelling the general tendency of self-interested human nature toward the realization of public purposes.

What is new about Legalist view of *fa* is that it is consciously designed to institute an automatic polity (see §6). Individuals are compelled to grasp the utilitarian logic of automatically and habitually moulding their behaviour in conformity with *fa*, not only as objective standards but also as prescriptive 'tools' of penal codes, so as to achieve their self-interested goals. Given self-interested human nature, once the prescriptive mechanism of penal codes is in place, human behaviour becomes automatic and predictable, just as Adam Smith's 'economic man' becomes predictable once a free market is established. Legalists envisage a habitual convergence of private and public interest which will become automatic in due course. It is clearly more in one's own interest to be rewarded for hard labour in farming and for valour in battle than to face the terrible consequence of behaving otherwise.

3 *Shi*: authoritative power base

Shen Dao (*fl. c.*310 BC), the Legalist best known for his theory of *shi* or authoritative power base, regarded *shi* as a 'natural position of advantage' *vis-à-vis* others. *Shi* is a charismatic and mysterious 'potency' (*de*) that inspires awe and obedience among the masses. It is *shi* that enables the flying dragon to ride the clouds and the soaring serpent to float in the mist. Without the *shi* of clouds and mist, the dragon and serpent might as well be earthworms (fr. 10). 'As a simple yeoman', without *shi*, even Yao, a pre-dynastic sage ruler, 'could not command his neighbours' (fr. 12), while Jie, the depraved last emperor of the Xia dynasty, because of *shi*, could wreak havoc on the whole world. In essence, Shen Dao was expounding the very phenomenon of authority, *conditio sine qua non* for an orderly and civilized society.

None the less, Han Feizi's critique of Shen Dao centres on the theory of 'natural position of advantage', obviously analogous to the Confucian view of 'superior moral qualities' of virtuous rulers (see Han Feizi). Confucians argue that it is the superior qualities of the dragon that enable it to soar, and it is the superior moral virtues of Yao that brought order and benefits to the world. The argument curiously ends with an observation: 'It belongs to man's essential nature that the worthy are fewer than the unworthy' (*Han Feizi* 40). If good government depends on the worthy, Han Feizi argues, the world is condemned to almost continuous disorder and misgovernment inasmuch as Yao only appears once in 'a thousand generations'. His concern is with the rulers in between the exceptionally virtuous Yao and the notoriously depraved Jie, that is, those who regularly occupy the position of *shi*.

For Han Feizi, then, good government depends not so much on 'superior moral qualities' of one who holds authority as on *shi* being 'properly ordered'; that is, *shi* securely based on clearly defined and promulgated laws that are rigorously enforced. In short, there exists a contradiction between *shi* based on 'positive' law and the imperatives of a 'higher' moral norm. Han Fei asserts that *shi* based on law and a moral code are mutually exclusive: 'A man selling spears and shields was praising his shields as so hard that nothing could penetrate them. Immediately afterwards, he said in praise of his spears "My spears are so sharp they will penetrate anything." When some one asked "What if I penetrate your shield with your spear?" he was at a loss to answer.' Han Feizi concludes: 'The two names [power and morality] cannot be made to stand [simultaneously]. The Way of the Worthy may not be forbidden, yet it is the Way of Power to forbid anything' (*Han Feizi* 40).

In Han Feizi's conception of *shi*, there is an unmistakable shift toward an institutionalized and impersonal authoritative power exclusively based on law, consciously designed by statecraft and bureaucratically administered under the ultimate sanction of 'the two handles'. Shen Dao too is aware of the human fallibility of those who wield authority and the need for objective standards: 'When one who rules men casts aside the laws and governs on his own initiative, the punishments and rewards, seizures and grants, will be measured out according to the discretion of the ruler' (fr. 61).

Shen Dao moreover affirms an important attribute of authority, namely, 'it has weight' because it 'receives aid from many' (fr. 14). 'That the power of the Three Kings [three dynasties of Xia, Shang and Zhou] and the Five Protectors [of the Spring and Autumn period] was the same order as that of Heaven and the Earth… was due to the fact that they obtained aid from all' (fr. 16). Han Feizi likewise affirms: 'When the ruler wins the hearts of the people', he elevates himself to the position of authority 'without being raised' because the ruler is 'upheld by the masses of people with united hearts' (*Han Feizi* 28). However, he asserts that the ruler's *shi* is upheld by the

masses not because of ‘natural position of advantage’ but rather because the well-ordered system of *fa* underpinning the ruler’s *shi* will in the long run bring order and benefits to the people. In the final analysis, Legalists placed greater emphasis on the impersonal and institutionalized *shi* of rulership firmly based on *fa* than on authority borne up by ‘natural position of advantage’ or ‘virtuous qualities’ of the ruler. The concept of the ‘consent of the governed’ as the basis of legitimate authority, of course, was never a part of Legalist elitism.

4 *Shu*: the art of rulership

As is true of any complex sociopolitical entity, the Legalist model of sociopolitical organization cannot function without authority, nor can a ‘properly ordered’ authority based on law govern well without an efficient bureaucracy. The ruler who wields authority must therefore master *shu*, the ‘method’ or ‘technique’ of controlling bureaucracy and its personnel.

Shen Buhai (d. 337 BC) is best known for his theory of *shu*, although *shu* as the arcanum of government had been an essential part of covert statecraft long before his theorizing about it. What is significant about Shen’s theory of *shu* is that it specifically sets forth a rational paradigm for bureaucratic accountability. Furthermore, it advances a theory of bureaucracy based exclusively on merit. Shen says: ‘"Method" is to scrutinize achievement and [on that ground alone] to give rewards, and to bestow office [solely] on the basis of ability’ (fr. 23).

Shen Buhai’s theory, elaborated by Han Feizi, argues that *shu* consists in holding officials accountable by impersonal application of objective and verifiable standards, so that an official’s actual ‘performance’ accords with the ‘name’ of the office held. He uses the term ‘tally’ to connote a method of precise calibration and verification. For instance, an official holds the debtor’s portion of a tally according to his title (‘name’), and he is accountable for actual performance that tallies with the creditor’s portion held by the ruler. Holding firm to the ‘main cord’, the ruler controls subordinates by means of the tallies. Both the metaphor of ‘main cord’ of a tightly-knit net (fr. 1(4)) controlling the tallies and the concept of ‘cutting deeply’ (fr. 27) as a means of holding subordinates accountable correspond to the Legalist concept of centralized control by holding fast to ‘the two handles’. Whenever a minister utters a ‘word’ (proposals), the ruler measures it against actual performance. If the actual performance indeed ‘tallies’ (*Han Feizi* 5) with the ‘word’, the minister is rewarded; if the performance does not ‘tally’ with the ‘word’, the minister is punished. Han Feizi’s exacting theory of accountability derives from his own experience as a prince of a ruling house. The critical observations and remonstrations throughout his writings are, in effect, diagnoses of the political pathology of his time and his prescriptions for remedying them. In particular, he addresses the problem of sovereigns being deluded by irresponsible eloquence that promotes partisan interests and weakens the state.

Han Feizi also drives home the harsh consequences of violating the requirements of functional specificity:

> Once in the past Marquis Chao [Zhao] of Han got drunk and fell asleep. The keeper of the royal hat, seeing that the marquis was cold, laid a robe over him. When the marquis awoke, he was pleased and asked his attendants, ‘Who covered me with the robe?’ ‘The keeper of the hat’, they replied. The marquis thereupon punished both the keeper of the royal hat and the keeper of the royal robe. He punished the keeper of the robe for failing to do his duty, and the keeper of the hat for overstepping his office. It was not that he liked the cold, but he considered the trespass of one office upon the duties of another to be a greater danger than cold.
>
> (*Han Feizi* 7)

How does Han Feizi or Shen Buhai know that the tallies match? The ruler’s *shu* is twofold: it consists of (1) empiricism and (2) purposive Daoism (see §6). While Shen Buhai speaks of ‘looking into affairs by means of their names’ (fr. 1(9)) and ‘careful supervision’ of subordinates (fr. 17(1)), he relies more heavily on the *shu* of purposive Daoism. Han Feizi emphasizes both and provides the most elaborated philosophical arguments for purposive Daoism. He stresses the need for the ruler to gather ‘causes of different affairs for comparison and observation’ (*Han Feizi* 17) and to follow ‘the procedures of comparison and verification to judge [actual performances]’ (*Han Feizi* 14), for ‘to be sure of anything that has no corroborating evidence is stupid’ (*Han Feizi* 50).

Fa and *shu* are different in that *fa* is overtly promulgated and primarily intended for regulating the behaviour of general public, whereas *shu* is the covert arcanum of government and primarily intended for controlling the

behaviour of bureaucracy. *Fa* and *shu* are similar in that they are impersonal and objective 'tools' for controlling human behaviour. Han Feizi criticized Shang Yang for having neglected *shu* and found Shen Buhai wanting for not having unified *fa*. *Fa*, *shi* and *shu* constitute the three interdependent pillars of Legalist philosophy.

5 Historical relativism

Shang Yang relates three different historical periods and their corollary behavioural and value patterns (*Shangjunshu* 1). Since the former generations did not share the same doctrines, he asks rhetorically, 'Which antiquity shall one imitate? The emperors and kings did not copy one another, so what rites should one follow?' (*Shangjunshu* 7). He saw more than one way to govern the world and found no need to imitate antiquity. He was quite prepared to institute new *fa* to remould the people (see §1).

Han Feizi elaborates on Shang Yang's historical relativism. Radical in thought and perceptive of what was to emerge in the wake of the systemic disintegration of the Zhou feudal order, he advances a new philosophy of history that directly challenges the traditional and characteristically Confucian 'Return to the Time of the Ancient Sages and Early Kings' philosophy of history (see History, Chinese theories of). His historiography divides the history of China into three eras: (1) remote antiquity, (2) the middle age and (3) the present age, each era having its distinctive character: 'Men of remote antiquity strove to be known as moral and virtuous; those of the middle age struggled to be known as wise and resourceful; and now men fight for the reputation of being vigorous and powerful' (*Han Feizi* 49). The difference between antiquity and 'the present age' is that in antiquity 'events were few' and 'measures were simple'. Because there were relatively few people, it was easier to make light of profit and to yield to others, 'But the present age is one of numerous affairs and great struggle' (*Han Feizi* 47). He succinctly summarizes his historical relativism: 'There are as many situations as there are generations' and 'situations change, so the measures change' (*Han Feizi* 49).

Han Feizi's historiography is iconoclastic in that he unmasks the irrelevance of the sacred precepts of ancient sages and early kings in and of themselves. He is primarily concerned with the effective ways of dealing with the reality of his own time according to the principle: 'situations change, so the measures change'. He confidently concludes that *fa*, understood as a new model of sociopolitical institutions with the corollary implications for behavioural change, is the most effective instrument for dealing with the reality of 'the present age' (see §6). In his historical relativism, the main emphasis is on the 'situations change', not 'measures change':

> Change or no change, the sage does not mind. For he aims only at the rectification of government. Whether or not the ancient traditions should be changed, whether or not the existing institutions should be removed, all depends upon the question whether or not such institutions and such traditions are still useful for present-day political purposes.
>
> (*Han Feizi* 18)

Therefore, he was judicious in avoiding indiscriminate rejection of the sacred precepts of the past merely for the sake of change. Rather, his criticism was directed against those who, while oblivious as to the 'condition of the wicked and the villainous' and clueless as to the effective means of rectifying the course of the state, blindly venerate the past and bewilder the ruler. Han Feizi's overriding concern was no less than 'to save the present age'; hence, he placed particular emphasis on 'politics of consequence', not unlike Max Weber's 'ethics of responsibility'.

6 The Legalist vision and Daoism

Despite historical relativism, the new model of Legalist institutions represents an ahistorical 'ideal type'. This paradigm of Legalist polity is consciously designed to incorporate certain aspects of Daoism so that, once established, it operates 'naturally' and 'automatically'. In short, this paradigm may be equated with the Legalist vision and response to the perennial question of 'what is the good society?' In contrast, Machiavelli was primarily preoccupied with the techniques of manipulating power and was less concerned with devising a new paradigm.

The Legalist search for objective, impersonal and impartial standards goes beyond a simple rationalization to justify political power. Han Feizi presents the most sophisticated philosophical inquiry into the relationship between Legalism and Daoism (see Daoist philosophy). He comments extensively on various sections of Laozi's *Daodejing* (see Daodejing) in chapters 20, 'Interpreting Laozi', and 21, 'Illustrating Laozi'. He writes: '*Dao* is

that from which all things are as they are, and it is the collecting point of all principles [*li*]' (*Han Feizi* 20). Things are essentially what they are because of their respective principles (*li*) (see Li).

Li etymologically refers to 'venation in pieces of jade'; hence, it symbolizes natural pattern and order that are independent of human thinking, willing and behaving. Rocks are hard; dogs bark; the four seasons run their course; day follows night; people are born and they die.

Water has its own nature: one who is drowning dies as one drinks too much of it, and one who is thirsty lives as one drinks a proper amount of it. Han Feizi's *li* represents the constants or 'objective regularities' in the natural order of things. Human beings may choose to accord with *li* or go against it at their own risk.

Shen Buhai says: 'Heaven's Way has no private [concerns] therefore, it is always correct' (fr. 8). It is the humans who must discern and conform to the constant *dao* to be 'correct', for *dao* 'embraces all opposites' and is not partial to human concerns (see Dao). It is *dao* that patterns the universe and is the source of *li*: '*dao* is the beginning of myriad things and the standard of right and wrong' (*Han Feizi* 5). Han Feizi sees the natural world and the human world in one continuum. The very same *dao* and *li* pervade both worlds, and it is by being informed by *dao* and *li* that the ruler is able to conform to the truly objective and natural order of things and realize the fullness of one's 'potency':

> The ancients who completed the principal features of Legalism, looked upon Heaven and earth, surveyed rivers and oceans, and followed mountains and ravines; wherefore, they ruled as the sun and the moon shine, worked as the four seasons rotate, and benefited the world in the way clouds spread and winds move.
>
> (*Han Feizi* 29)

Thus, the ruler should model after *dao* and govern according to *dao*'s objective standards by not acting (*wuwei*) contrary to the natural order of things and by cultivating 'emptiness' and 'quiescence' so as to embody *dao*. In so doing, the ruler acquires the 'potency' (*de*) for governing (see De). Han Feizi advises the ruler to be 'humble'; this means not only refraining from overindulgence in seeing and hearing but also moderating mental activity. In short, it means bringing one's sensual and heart-mind activities under control so that one knows how to 'conserve'. By knowing how to 'conserve' through restraining his subjective inclinations, the ruler is better able to accord with *dao* and *li*.

Having instituted the new model of Legalist polity according to the objective and impersonal standards of *dao* and the natural feelings of 'likes' and 'dislikes' of human nature, the sage ruler reposes in 'non-action' (*wuwei*): 'He remains empty and waits for [the subordinates'] service, and they will exert [*yuwei*] their abilities by themselves' (*Han Feizi* 8). Thus, a *wuwei*-*yuwei* dialectical relationship marks the functional differentiation of the ruler and the subordinates. The ruler, uniquely personifying *dao* and grasping 'the two handles', reposes in *wuwei*, while the subordinates actively engage in fulfilling their *xingming* accountability. The sage ruler, by his gnostic grasp of *dao*, knows the source of everything and, by being in accord with objective standards, knows the 'origin of good and evil'. Such a ruler, by practising *shu* of 'emptiness' and 'quiescence', waits for all 'names' to name themselves and all 'affairs' to settle themselves as though automatically (*Han Feizi* 5). Han Feizi resorts to metaphors to clarify the *shu* of 'non-action': like the stationary mirror, the ruler can see and compare the beautiful and the ugly; like the centre point of the scale, he can weigh the light and heavy without moving (*Han Feizi* 19).

Is this comparing and weighing truly automatic? However 'natural' and 'automatic' the new paradigm of Legalist polity may seem, in the final analysis, the ruler does not act *so that* he can act, and Legalist polity requires a ruler who is exceptionally adept at covert techniques of statecraft. Like the Smithean theory, the Legalist idea of 'automatic society' proved to be illusory.

7 Enduring significance of Legalist philosophy

First, Han Feizi's drawing a parallel between Heaven and the ruler is highly symbolic, for it implies the ruler's uniqueness beyond the ordinary social hierarchy. To accentuate this uniqueness, he pushes the comparison to its ultimate level, drawing an analogy between *dao* and the ruler: '*Dao* is never a pair. Hence it is called one. Therefore, the intelligent ruler esteems singleness, the characteristic of *dao*' (*Han Feizi* 8). Just as *dao* does not identify with myriad things, accordingly the ruler sets himself apart from his ministers and people. It is in this conscious personification of *dao* that the ruler transcends the rest and achieves uniqueness. This uniqueness in turn

endows him with an extraordinary power to bring all affairs under control (*Han Feizi* 29). Han Feizi may well be basing his theory of the ruler's uniqueness on Chapter 25 of the *Daodejing*: 'Hence the way [*dao*] is great; heaven is great; earth is great. Within the realm there are four things that are great, and the king counts as one.' He may also base his philosophical argument for the ruler's extraordinary power to control all affairs on Chapter 14 of the *Daodejing*: 'Hold onto the *dao* of old in order to master the things of the present' (see Daodejing).

Thus, Han Feizi provided the most sophisticated philosophical justification for autocracy. The enduring significance of Han Feizi's Legalist philosophy is the legacy of two millennia of autocracy in China. Despite the dominance of Confucian orthodoxy, the political institutional framework of autocratic, centralized power has been essentially Legalist. Further, China is and has been an eminently bureaucratic society. Shen Buhai and Han Feizi's rational paradigm for bureaucratic accountability and merit-based functional specificity - for better or worse - has shaped the Chinese pattern and rhythm of life up to the present day. Of course, there were also strong departures from the Legalist model. However, after the eighteenth-century *philosophes* took a fancy to the Legalist model of bureaucracy based on merit, Shen Buhai may be considered 'the ancestor' of a worldwide institution of bureaucracy (Graham 1989). Lastly, the covert tradition of political technique (*shu*), inspired by purposive Daoism, namely 'non-action' as well as decisive action according to 'timeliness', continues to remain a significant aspect of Chinese philosophy of governing and political culture.

Legitimacy

Legitimacy refers to the rightfulness of a powerholder or system of rule. The term originated in controversies over property and succession, and was used to differentiate children born of a lawful marriage from those who were 'illegitimate'. From thence the term entered political discourse via controversies over the rightful succession to the restored French throne after the Napoleonic period. However, questions about what makes government rightful have been a central issue of philosophical debate since the ancient Greeks, and in this sense the concept, if not the term, 'legitimacy' is as old as political philosophy itself. Its significance lies in the moral, as opposed to merely prudential, grounds for obedience which follow for subjects where power is rightfully acquired and exercised, and in the depth of allegiance which such political authorities can call upon in times of difficulty.

What, then, makes government legitimate? Most thinkers agree that a necessary condition is that power should be acquired and exercised according to established rules, whether these are conventionally or legally defined. However, legal validity cannot be a sufficient condition of legitimacy, since both the rules and the power exercised under them also have to be morally justifiable. Two broad criteria for moral justifiability can be distinguished: (1) political power should derive from a rightful source *of authority; (2) it should satisfy the rightful* ends *or purposes of government. Most philosophical disputes about legitimacy take place either within or between these two broad positions; any adequate account of it must embrace both however.*

1 The source and ends of political authority

Historically, claims made for the rightful source of political authority have been enormously diverse, including: divine authority, mediated via religious doctrine and its interpreters; tradition and the principle of continuity with a society's past; some infallible truth, such as Marxism-Leninism, about society's future destiny and its chosen agents; and the people as a whole, and the principle of popular sovereignty. Although the first of these is still defended within parts of the Islamic world, most Western political philosophy of the modern era has sought to establish a secular source for political authority. With the authority of tradition relegated to at most a secondary plane, and Marxism-Leninism now discredited, the principle of popular sovereignty is virtually uncontested in the contemporary world. Much room for disagreement remains, however, about which constitutional arrangements best realize this principle; and - between competing conceptions of nation and nationalism - about who precisely constitutes the people that is the source of political authority (see Nation and nationalism).

The alternative idea - that legitimate authority is one which realizes the rightful ends or purposes of government - has historically produced an equally varied set of criteria, according to how these ends or purposes have been defined: whether government exists to guarantee basic societal needs for security and subsistence; to realize some ideal conception of the good society and virtuous citizenship; or to protect specified individual rights. However, a common feature of any 'performance' criterion of legitimacy, even more clearly than for the first definition, is to establish a standard against which individual rulers or regimes can be assessed, and, where need be, found wanting. That is to say, theorizing about legitimacy typically has a critical, rather than a merely apologetic purpose; and it tends to flourish when the authority of government is already uncertain or contested (see Authority).

2 Social contract theories

The two broad types of legitimating criteria considered above - the source and the ends of political authority - were brought together in the early modern period by theorists of the social contract, such as Hobbes and Locke. According to social contract theory, government was a product of conscious human artifice; its legitimacy derived from its authorization by the people themselves. At the same time the deficiencies of the pre-governmental 'state of nature', which led people to enter into the social contract, both defined the proper purposes of government and also set limits to its legitimacy: according to Hobbes (1651), through the provision of physical security; according to Locke (1689), through the protection of natural rights and the rule of law. Where these purposes were manifestly broken, the obligation of subjects to government was at an end. For both writers, then, where popular authorization established the *grounds* of legitimate rule, the true purpose of government defined its *limits* (see Contractarianism §2, 5).

Subsequent critics of the two writers pointed to their arbitrary characterization of the state of nature from which the ends of government were to be derived. They also questioned whether (given that one took place) a once-for-all authorization of government through the social contract could conceivably serve to legitimate political authority for subsequent generations. Locke rightly rejected Hobbes' contention that contracts made under the duress of conquest were valid. However, his own notion of 'tacit consent', whereby those who chose not to leave the country or disown their inheritance were presumed to have agreed to the existing governmental arrangements, hardly constituted a robust condition for popular consent to, or authorization of, government (see Consent §2).

In his work *The Social Contract*, Rousseau §3 claimed to have remedied the deficiencies in previous contract theorizing (Rousseau 1762). Political authority could be legitimate, he argued, only where citizens had the right to vote in person on legislation and where the executive was directly accountable to the sovereign legislative assembly. Whereas previous consent theory offered citizens no effective choice about accepting existing governmental arrangements, the unlimited legislative authority Rousseau gave his citizen body provided it with the continuous opportunity to modify received social and political rules. It could therefore meet the most strenuous conditions for popular consent to government. However, these conditions were bought at a price: a radical inequality of citizenship status between the sexes and the impracticality of direct legislation outside small-scale societies. If people could never autonomously consent to a representative system, then where could legitimate government realistically be found? Moreover, Rousseau's implausible contention that those who voted against any legislative proposal in the sovereign assembly had in some sense really willed it enabled him to evade the need to set constitutional limits to the scope of legislation, or to guarantee protection for individual or minority rights (see General will §§1-2).

3 'Performance' criteria of legitimacy

The cul-de-sac which social contract theory seemed to have reached with Rousseau led most subsequent thinkers to develop the second 'performance' dimension of legitimacy. For the utilitarians, the sole test of a rightful system of government lay in its capacity to promote the 'greatest happiness of the greatest number' (Bentham 1776, 1778) (see Bentham, J.). Democratic arrangements were to be defended, not on the principle of popular sovereignty, but only in so far as they served to protect the interests of the large majority against the sectional interests of the few (Mill 1821), or to develop those active qualities of citizenship which would enable people to relate their own interests to those of society as a whole (Mill 1861) (see Mill, J.S.). In contrast, idealist thinkers from Hegel to Green defined the purpose of government in more exclusively ethical terms: to develop the highest moral form of life for society. The rightful form of government was that which would be most conducive to this end.

'Performance' criteria of legitimacy have also been at the fore in recent political philosophy, albeit in a modified form of social contract theory. In the work of Rawls, J. and his followers, the idea of the social contract is purely hypothetical: it is a device for establishing what social and political arrangements people *would* agree to, if they could imagine themselves ignorant of the social positions they would occupy or the individual characteristics and preferences they might possess (Rawls 1971). From this imagined pre-political condition we can then derive a list of basic rights and freedoms and criteria for fair decisional procedures which should command universal assent. What makes government legitimate on this view is not its *actual* authorization by the people, but its conformity to standards which they *would* authorize if they were truly impartial.

4 Legitimacy and liberal democracy

Rawls' work comes close to characterizing the underlying principles of a liberal-democratic order. As a theory of legitimacy, however, it is inadequate, being too one-dimensional. To satisfy the principle of popular sovereignty, a liberal-democratic regime has to meet criteria for the *actual* authorization of government by the people: not only through the regular, free and fair election of public officials in conditions of electoral equality, but also through the realistic opportunity to modify received constitutional arrangements by means of referendum and citizens' initiative. Only the combination of these conditions could plausibly meet the criteria for popular consent and authorization which social contract theory was aiming for, but failed to achieve. At the same time, the liberal-democratic state has also to meet continually evolving standards for the protection of individual rights and guarantee of social welfare if it is to satisfy defensible performance criteria of legitimacy (see Democracy).

Any adequate philosophical account of legitimacy, therefore, has to consider both the rightful source and ends of

political authority; legitimate government must meet criteria of authorization and performance standards together. To recognize this is to identify one of the characteristic dilemmas of liberal democracy: the two dimensions of legitimacy may conflict with, as well as reinforce, one another. The governments and political arrangements that people actually choose to authorize may fail to meet defensible standards of fairness or rights protection for all citizens. This is because empirical persons with definable beliefs and interests differ in practice from the disembodied agents of a hypothetical social contract; and the circumstances of actual decision making can be far removed from the impartiality or Habermas' 'ideal-speech situation' of a pure legitimacy (see Habermas, J.). This tension is at its most acute in the conflict between forms of ethnic and particularistic self-definition of a people as a self-governing nation, on the one hand, and the universalistic standards implicit in any justifiable defence of individual rights or democratic citizenship, on the other.

5 Social science and legitimacy

Whereas a tendency of philosophical accounts of legitimacy is to dissolve the tensions between different legitimating principles by positing a transcendental world of impartial citizens inhabiting the good society, the tendency of social science accounts lies in a different, reductionist direction: to reduce legitimacy to whatever a given people *believes* to be legitimate. Social scientists are interested in legitimacy as an explanatory rather than a normative concept: to help explain why people actually obey authority, rather than why or when they should; why regimes actually persist, rather than whether they deserve to. From this perspective legitimacy tends to become, not a quality of regimes or governments, but an attribute of subjects: their internalized 'belief in legitimacy' (Weber 1914). Regimes are legitimate if they are able to generate and maintain the appropriate state of mind in their populations (Lipset 1960). Such an account produces a radical disjuncture between the projects of political science and political philosophy; analysing the empirical processes of *legitimation* comes to replace the construction of defensible criteria for *legitimacy*.

Social scientists can only escape from this reductionist dead-end if they acknowledge the same conceptual structure to legitimate power as do philosophers - as a matter of conformity to rules which are themselves justifiable in terms of specific beliefs about the rightful source and ends of political authority - and if they see the process of legitimation to lie in the actions of relevant subjects confirming their support for the regime or its powerholders (Beetham 1991). Equipped with this conceptual structure, social science can then make its own distinctive contribution to the study of legitimacy: through a comparative analysis of different legitimating principles and processes in different societies and epochs, and of the way these are embedded in institutional structures and practices; through an identification of the gaps that may develop between the underlying principles of a regime and their supporting beliefs, on the one hand, and its actual practice on the other; and through an examination of the processes of de-legitimation which may herald its collapse.

A comparative analysis of this kind can also serve to complement a philosophical account of liberal-democratic legitimacy by exploring why it tends to win out in competition with other legitimating principles, especially once a population attains a developed level of education and literacy. At this point the explanation of why societies come to have the legitimating principles they do cannot be divorced from the defensibility of their grounds for holding them; and such principles must be recognized as legitimate in a context of international, not merely national, scrutiny and debate. In the explanation of legitimacy, in other words, the projects of normative philosophy and a non-behaviouristic social science can be seen to become one and the same.

Leibniz, Gottfried Wilhelm (1646-1716)

Leibniz was one of the central figures of seventeenth-century philosophy, indeed, one of the central intellectual figures of his age. Born and educated in Germany, he travelled to Paris in 1672 and quickly entered into its lively intellectual and scientific life, acquainting himself with the most advanced ideas then in circulation. It was there that he invented the infinitesimal calculus, and laid the foundations for the philosophical and scientific programmes that were to occupy him for the rest of his life. He returned to Germany in 1676, entering the service of the House of Hanover where, except for brief absences, he remained until his death. There, along with his court duties, he had time for a wide variety of intellectual activities that eventually gained him an international reputation.

Leibniz's philosophy, particularly his metaphysics, can appear otherworldly and complex. But there are a few simple themes and basic commitments that run through his thought. At root is his philosophical optimism, the commitment that this is the best of all possible worlds, freely created by a rational God who always chooses the best for a good reason. This best of all possible worlds, Leibniz held, is 'the one which is at the same time the simplest in hypotheses and the richest in phenomena' (Discourse on Metaphysics §6). For this reason, the world must be governed by a variety of general principles to which Leibniz appealed in his philosophy: there must be a sufficient reason for everything in the world; there are no jumps in nature; there must be exactly the same power in the full cause as there is in the complete effect, among many others. While such principles do not deductively determine the rest of Leibniz's philosophy, they do play a major role in shaping it; they constitute a kind of lens through which he viewed the major philosophical issues of his age.

One such issue concerns the ultimate make-up of the world. Like many of his contemporaries, Leibniz adopted a mechanistic view, according to which everything in the physical world is explicable in terms of the size, shape and motion of the tiny bodies that make up the grosser bodies of experience. But he rejected the idea that this could be the ultimate explanation for things. Behind the mechanistic world of inanimate bodies in motion, Leibniz saw a world of living things and souls - active, genuinely individual, genuinely different from one another, the true atoms of nature, the true reality - which he eventually called monads. At the deepest level, Leibniz's world was made up of an infinity of mind-like entities, each with its own perceptions that change from moment to moment according to an internal programme by way of the faculty of appetition, all in harmony with one another so that they all reflect the same world. While the world of physics is mechanistic, it is merely phenomenal, the confused appearance of a deeper reality. A consequence of this was Leibniz's famous doctrine of pre-established harmony. In contrast to Descartes, for whom mind and body interact, and in contrast to the occasionalists, for whom God is the true cause who brings about motion in the body on the occasion of a volition and a sensation in the mind on the occasion of a stimulation of the appropriate nerves in the body, for Leibniz God created the mind (a single monad) and the body (itself a collection of monads) in perfect harmony with one another so that their mental and physical states would always correspond in the appropriate way.

A second set of metaphysical issues of central concern to Leibniz involves the interlocking questions of necessity, contingency and freedom. In response to contemporaries such as Hobbes and Spinoza, Leibniz tried to find room for contingency and freedom in his world. He argued that even though God is, in a sense, constrained to choose the best, he does so freely. Consequently, the world he created, the best of all possible worlds, exists contingently, and at least some features of it are contingent, those whose contraries are not in themselves impossible. So for example, 2 + 3 = 5, true in every possible world, is necessary, while 'Adam sins', whose contrary is not impossible, is contingent. But over and above contingency and divine freedom, Leibniz also wanted to make room for human freedom. According to Leibniz, when God created Adam as a part of this best of all possible worlds, he knew that Adam would sin; it is part of the concept of Adam that he sins, part of his internal 'programme' that he will eat the apple, and part of the internal 'programmes' of the monads that make up his body that he will actually eat the apple. But, Leibniz argued, what God builds in is that Adam freely *chose to sin. God builds into the world the reasons that incline Adam's will without necessitating it, correctly predicting what Adam will do, and building the rest of the world around the consequences of Adam's free actions.*

Important as they are, these two concerns constitute only a small portion of Leibniz's thought, even within the domain of philosophy. In psychology, he introduced a distinction between conscious and unconscious perceptions

and tried to understand the way in which unconscious perceptions (‘petites perceptions’) in part determine conscious perceptions (‘apperceptions’). In epistemology, he is important for his sophisticated version of the innatist hypothesis, and for appreciating the role that a mathematical theory of probability can play in understanding the world. In logic, Leibniz advanced programmes for a new formal logic more powerful than Aristotle’s, and for a universal language. In ethics and political thought, he contributed to the seventeenth-century natural law tradition. In natural philosophy, he emphasized the importance of the notion of force and advanced the broadly Cartesian programme of a physics grounded in conservation laws. Outside philosophy he is well known for his work on the calculus. Though he co-discovered it with Newton, it is his notation that is still used, and his version probably had the greater influence in his day. But he was a major contributor to many other fields, including geology, natural history, linguistics and European history. Though he left no real school of followers, he deeply influenced philosophy after his death, particularly in eighteenth-century Germany.

1 Life

Gottfried Wilhelm Leibniz was born in Leipzig on 1 July 1646. He later recalled how his father, who died when he was only six years old, had instilled in him a love of learning. Leibniz started school when he was seven, but more important than his formal education in those years was his reading. He taught himself Latin at an early age in order to be able to read Livy and Calvisius, and because of that was admitted into his late father’s extensive library, where he read widely. At fifteen Leibniz entered University, first the University of Leipzig (1661-66), and then the University of Altdorf (1666-67), graduating with degrees in law and in philosophy. The education he received there was conservative, a mixture of traditional Aristotelian school philosophy and Renaissance humanism. Though invited to join the faculty at Altdorf, he chose instead to enter the service of the Elector of Mainz, where he stayed until he was sent to Paris in the spring of 1672 on diplomatic business.

While he had done significant work in a number of areas before going to Paris, including law, theology, mathematics and physics, the trip was crucial to Leibniz’s intellectual development. In the later part of the seventeenth century, learned Europe was in the midst of a great intellectual revolution; the older Aristotelian philosophy of the schools was being challenged by a new mechanist philosophy which rejected the form, matter and qualities of the Aristotelian world, replacing them with a world in which everything was to be explained in terms of size, shape and motion. In this new world there was a special emphasis on mathematics, which was increasingly applied to problems in physics in a way quite foreign to the Aristotelian philosophy.

Though he had taken an interest in the moderns while in Germany (Hobbes was particularly influential on his early thought), it was only after he reached Paris that Leibniz was able to enter the mainstream of European intellectual life. There he came to know the important mathematician and physicist Christiaan Huygens, who introduced him to new ideas which Leibniz absorbed quickly. In those years, Leibniz laid the foundations of his calculus, his later physics and his philosophy. While there were no publications at the time, many unpublished notes survive, important for understanding the emergence of his mature thought.

Leibniz returned to Germany in December 1676, passing through Holland, where he discussed philosophy with the reclusive Spinoza. It was then that he first entered the service of the House of Hanover. He served under Duke Johann Friedrich until his death in 1679, under Duke Ernst August from 1680 to 1698, and then, finally, under the Elector Georg Ludwig, who ascended the throne of Great Britain as King George I in 1714. Except for his travels, he remained at Hanover for the rest of his life. There Leibniz undertook a very wide variety of tasks. He served as a mining engineer (unsuccessfully supervising the draining of the silver mines in the Harz Mountains), as head librarian of a large collection of books, as a general advisor and a diplomat, and was particularly interested in finding ways for the Catholics and the Protestants to reunite. Leibniz was also given the responsibility for writing a history of the House of Hanover. While he collected and published many previously unknown historical documents and published a number of other historical writings, this project barely got off the ground. All that he seems to have completed was a geological history of the region of Lower Saxony, the *Protogaea*. While it proved to be an important work in the history of geology when it was finally published in 1749, it seems not to have pleased Leibniz’s employers who had hoped for a history of somewhat more recent times.

Through the rest of his life, Leibniz continued to explore the philosophical, scientific and mathematical questions that interested him from his earliest years. The 1680s and 1690s saw some of his most important writings. In these years, he published his new infinitesimal calculus and a variety of papers outlining his new approach to physics,

particularly his new science of dynamics, the science of force and its laws. The *Brevis demonstratio* of 1686 presents for the first time a refutation of Descartes' conservation law, and hints at the foundations of a more adequate physics. The details are developed in his unpublished *Dynamica* (1690), some material from which is published in the *Specimen dynamicum* in 1695, as well as in the numerous answers to attempted refutations of his argument from tenacious Cartesians. In philosophy, Leibniz published his *Meditationes de cognitione, veritate et ideis (Meditations on knowledge, truth and ideas)* in 1684, and in 1686 composed the *Discours de métaphysique (Discourse on metaphysics)*, eventually published in 1846; the main arguments from the latter are discussed in a series of letters with the Catholic theologian Antoine Arnauld, letters Leibniz contemplated publishing in later years. These same themes are found, somewhat transformed, in two important publications in the 1690s, the *Système nouveau de la nature et de la communication des substances (New system of the nature and the communication of substances)* (1695b) and the *De ipsa natura (On nature itself)* (1698). In the first decades of the next century, Leibniz continued to be very active. Important in these years were the *Nouveaux essais (New essays)* (1704), a close examination of Locke's *Essay Concerning Human Understanding*, abandoned at Locke's death and unpublished until 1765. But he did publish his *Théodicée (Theodicy)* (1710), a compendium of philosophical and theological ideas involving further development of themes that go far back in his thought. His final philosophical works were short summaries, intended only as brief guides to his work, the *Monadologie (Monadology)* and the *Principes de la nature et de la grâce (Principles of nature and grace)*, both of which probably date from 1714.

Throughout these years Leibniz kept up a vast correspondence, including exchanges with Huygens, Johann Bernoulli, Burchardus de Volder and Bartholomaeus Des Bosses, among many others. One exchange is particularly important. Leibniz had been at war with his English counterpart, Sir Isaac Newton, for many years; their rivalry went back to at least the early 1690s, and probably to their first contact in the mid-1670s. The affair was ugly, with accusations of plagiarism regarding the calculus from both sides, and bitter disagreements over the foundations of physics. The rivalry finally resulted, in 1715-16, in a correspondence between Leibniz and Samuel Clarke, the latter standing in for Newton himself (see Clarke, S. §3). The exchange was published by Clarke in 1717.

When his employer Georg Ludwig went to London in 1714 to take the throne of Great Britain, Leibniz did not follow. He was out of favour for his failure to make progress on the history of the House of Hanover, as well as for his generally old-fashioned manner. Furthermore, it is likely that Georg feared that the dispute with Newton and the British intellectual establishment would cause difficulties. Whatever the reason, Leibniz remained in Hanover, where he died on 14 November 1716. Though celebrated in his life and considered a universal genius for the breadth of his interests and activities, in death he was virtually ignored, buried with little ceremony in a grave that was to remain unmarked for many years.

2 The programme

Leibniz never wrote a single work, book or article, that constitutes a canonical exposition of his thought, preferring the short article or letter where he presents his thought from one or another point of view, often in response to the thought of another (Descartes was a favourite target), or in response to questions from a correspondent. Indeed, Leibniz's complex thought seems to resist the kind of comprehensive treatment found in works like Descartes' *Meditations* or Spinoza's *Ethics*. Furthermore, it is only to be expected that Leibniz's beliefs changed over his long career, and from one presentation of his philosophy to another.

Despite its complexity, there are some themes and characteristics that run throughout Leibniz's thought, at least in the mature period that starts after his return from Paris in the late 1670s, the period on which this entry concentrates. (While there was not a radical break from the early years to the later, there is certainly a marked development.) Basic to his thought was his philosophical optimism: this is the best of all possible worlds, freely created by a rational God, who always chooses the best for a good reason, without any arbitrariness. It is because of our limited understanding that we cannot determine a priori all the general or particular features of this world. This conception of God and his creation shaped Leibniz's philosophy: the world is ultimately both rational and in every way perfect. Furthermore, though Leibniz's philosophical intelligence ranged widely, certain problems were particularly important to him. In an untitled note from the late 1680s he wrote: 'there are two labyrinths of the human mind, one concerning the composition of the continuum, and the other concerning the nature of freedom, and they arise from the same source, infinity' (Leibniz 1989: 95). The labyrinth of the composition of the

continuum concerns the ultimate make-up of the world; the labyrinth of freedom concerns how freedom and contingency are possible in the world. The solution to both involves understanding the literally infinite complexity found in the world God created. Leibniz had an opinion about virtually every philosophical and scientific issue of his day, but these two issues consistently drew his attention.

3 God: creation and theodicy

Like many of his contemporaries, Leibniz thought that the existence of God could be proved, and he was particularly attracted by the so-called Ontological Argument, invented by Anselm and revised by Descartes (see God, arguments for the existence of §§2-3). According to the Ontological Argument, as given by Descartes and paraphrased by Leibniz in *Meditations on knowledge, truth and ideas* (([1684a] 1989: 25), 'whatever follows from the idea or definition of anything can be predicated of that thing. Since the most perfect being includes all perfections, among which is existence, existence follows from the idea of God…Therefore existence can be predicated of God'. Leibniz's contribution to the argument is the observation that, as it stands, the argument is not valid: 'from this argument we can conclude only that, if God is possible, then it follows that he exists'. For the argument to work, we must establish the self-consistency of the definition of God. But the consistency of the definition of God follows directly from the fact that God 'is without limits, without negation, and consequently without contradiction' (*Monadology* §45). In addition to this version of the ontological argument, Leibniz also used a cosmological argument for the existence of God, arguing from the existence of contingent things in the world, things whose reason lies outside of themselves, to the existence of a necessary being (*De rerum originatione radicali (On the ultimate origination of things)* (1697); *Monadology* §45). Finally, Leibniz argued from the existence of eternal truths: 'Without [God] there would be nothing real in possibles, and not only would nothing exist, but also nothing would be possible' (*Monadology* §43).

In the opening sections of the *Discourse on Metaphysics* (1686b: §6), Leibniz argued that 'God has chosen the most perfect world, that is, the one which is at the same time the simplest in hypotheses and the richest in phenomena', a formula that recurs often in his writings. While this is the main account of creation, in other texts, particularly the essay *On the ultimate origination of things*, he argued that 'there is a certain urge for existence or (so to speak) a straining toward existence in possible things or in possibility or essence itself; in a word, essence in and of itself strives for existence' Leibniz [1697] 1989: 150). Leibniz continued: 'From this it is obvious that of the infinite combinations of possibilities and possible series, the one that exists is the one through which the most essence or possibility is brought into existence'. Such an account of creation has the apparent implication that God is not necessary for it, and that creation results from a quasi-mechanistic weighing of possibilities with respect to one another. But Leibniz emphasized that God is the ground of all possibles, and that it is God who ultimately actualizes the possibles that 'win' the 'contest'. The 'striving possibles' account of creation would seem to be a metaphorical way of expressing Leibniz's usual account in terms of God's choice of the best of all possible worlds.

Leibniz's account of creation had a number of important implications. First, against Descartes and Spinoza, it entailed that there is a standard of goodness and perfection that exists independently of God; God creates the world because it is good, a world which is good not just because it is the creation of God (*Discourse* §2). Furthermore, unlike Malebranche, Leibniz held that the world could not have been created better than it is (*Discourse* §§3-4). Leibniz's doctrine of creation can also be read as a direct attack against a conception of God argued by Spinoza. Central to Spinoza's enterprise in the *Ethics* is an attack on the view that God is like us, that he has aims and goals, that he chooses things for a reason, and that he is bound by standards of goodness that exist independently of his will. This anthropomorphic view of God, Spinoza argued, is an illusion, a projection of our own nature onto nature at large (see Spinoza, B. de §4). Against Spinoza, Leibniz presented his own God, who deliberately chooses to create this world for a particular reason, because it is the best of all possible worlds, a reason intelligible to us. It is on this basis that Leibniz argued against both Descartes and Spinoza for the importance of final causes in nature.

Leibniz's account of creation also addressed the problem of understanding divine justice, in particular, how sin, evil and suffering are possible in a world created by God - the 'theodicy' problem, to use the word coined by Leibniz. His answer was complex, filling many pages in *Theodicy*, the only philosophical book he published in his lifetime. Briefly, his argument was that evil is a necessary and unavoidable consequence of God's having chosen to create the best of all possible worlds. However bad we might think things are in our world, they would be worse

in any other.

Leibniz’s account of creation was closely connected with a number of his key principles, most prominently the Principle of Sufficient Reason. As he wrote later in the *Monadology* (§53), ‘since there is an infinity of possible universes in God’s ideas, and since only one of them can exist, there must be a sufficient reason for God’s choice, a reason which determines Him towards one thing rather than another’. The Principle of Sufficient Reason entails that the universe is in principle rational and intelligible: God must always act for a reason, and as a consequence, there must be a reason for everything. But the account of creation was also connected with a number of other principles in Leibniz’s philosophy (discussed below). In this way one can say that the doctrine of creation underlies all of Leibniz’s philosophy. Had we God’s intellect, we would be able to derive all of the features of this world directly from its being the best of all possible worlds. As it is, our understanding of God’s creation will enable us to fix certain general truths about this world, and set certain bounds on our hypotheses about the way things are.

Leibniz’s interest in philosophical theology was not just the interest of a philosopher. He believed that his understanding of truths about God and nature would greatly assist the undertaking of uniting the Catholic and Protestant Churches under the umbrella of the true philosophy.

4 Metaphysics: substance, monad and the problem of the continuum

Leibniz is famous for his claim that he solved the problem of the composition of the continuum. In so far as the continuum (length, area, volume) is divisible, it would seem to be made up out of parts. But what parts could make it up? If the parts are extended (like atoms), then they too are divisible, and we require an account of their composition as well. On the other hand, if the parts are non-extended (like points), then it is difficult to see how they could make up an extended magnitude. Leibniz’s solution was this: the mathematical continuum should not be thought of as being *composed* of parts at all; while it has parts, those parts are the result of the division of the whole, and thus are posterior to it. On the other hand, Leibniz claimed, while real physical extensions have parts, there are no physical continua. Physical extended things are at root discrete multitudes whose constituents are substances (‘Remarques sur les Objections de M. Foucher’ (Remarks on the objections of M. Foucher) (1696); (Leibniz to de Volder, 19 January 1706). This raises one of the central problems for Leibniz’s philosophy: what are these substances that constitute the metaphysically ultimate constituents of the world?

While there are many paths into his views on substance, Leibniz’s critique of Descartes’ notion of corporeal substance is a convenient starting place. Descartes held that the essence of body is extension. What this meant is that bodies are geometrical objects made concrete, entities that have no properties that are not grounded in extension. Colour, taste, sound and so on are not themselves in bodies, but are only sensations in minds caused by our interaction with extended substances. While Leibniz as a mechanist agreed with this last claim, he rejected the Cartesian conception of body on which it is based (see Descartes, R. §§8, 11).

Leibniz offered a number of arguments against the Cartesian conception of bodily substance: (1) The notion of extension presupposes some quality that is extended, like whiteness in milk or resistance to new motion in every body, and so is not the kind of thing that by itself could constitute the essence of anything (Leibniz to de Volder, 30 June 1704; ‘Note on Cartesian natural philosophy’, 1702). (2) In so far as extended things are divisible, they are aggregates made up out of parts. But the reality of the aggregate presupposes some genuine individuals of which the aggregate is composed; no such individuals can be found in Cartesian bodies (Leibniz to Arnauld, 30 April 1687; *Monadology* §§1-3). (3) If the world is full and there are no vacua, and if the world is filled with Cartesian extended substance, then there can be no change in the world. For any supposed change would consist in one portion of body replacing another, identical in every way (‘On nature itself’). (4) If body were just extension, then it would be perfectly inert, and would have to be moved by God. If so, then God’s creation would be imperfect for lacking creatures which cannot themselves carry out any of God’s commands. Indeed, such a world would reduce to Spinoza’s world in which finite things are just modes of God (‘On nature itself’). Because of arguments like these, Leibniz wanted to take the Cartesian mechanist analysis of body back one step further, and resolve even extension into something more basic still, a world of substances that are genuinely individual, genuinely active, and which contain properties that distinguish individual substances from one another.

While there are a number of important discussions of the nature of substance in Leibniz’s writings, two are

especially noteworthy: the one he gave in the *Discourse on Metaphysics* at the start of his mature period, and the one he gave at the very end of his life in the *Monadology*. (There is a third important conception of substance that arises in the dynamical writings, discussed below in connection with his physics.)

Leibniz begins Section 8 of the *Discourse on Metaphysics* by noting that ‘it is evident that all true predication has some basis in the nature of things, and that, when a proposition is not an identity, that is, when the predicate is not explicitly contained in the subject, it must be contained in it virtually’. (This principle, which probably derived from Leibniz’s logical studies a few years earlier, was closely connected with the Principle of Sufficient Reason in Leibniz’s mind; the containment of the concept of the predicate in the concept of the subject constitutes the ‘sufficient reason’ for the truth of a proposition. This connection with his logic has caused some commentators to see Leibniz’s metaphysics as fundamentally logical in its inspiration.) And so, Leibniz claims, ‘the subject term must always contain the predicate term, so that one who understands perfectly the notion of the subject would also know that the predicate belongs to it’. He concludes that ‘the nature of an individual substance or of a complete being is to have a notion so complete that it is sufficient to contain and to allow us to deduce from it all the predicates of the subject to which this notion is to be attributed’. Since he held that there must be something in the substance itself in virtue of which this complete notion holds of it, he also concludes that at any given time, a substance must contain marks and traces of everything that is true of it, past, present and future - though only God could see them all. (It is not clear whether this committed Leibniz to holding that all properties of a given individual are essential to that individual, making him a kind of ‘superessentialist’, or whether he takes the weaker position that they are merely internal to the individual, making him a ‘superintrinsicalist’. Opinions differ among the commentators.)

In the *Monadology* Leibniz offers a somewhat different characterization of substance. Using the term ‘monad’ that he adopted to express the notion of an individual substance in the late 1690s, he expounds: ‘The monad…is nothing but a simple substance that enters into composites - simple, that is, without parts. And there must be simple substances, since there are composites; for the composite is nothing more than a collection, or aggregate, of simples. But where there are no parts, neither extension, nor shape, nor divisibility is possible. These monads are the true atoms of nature and, in brief, the elements of things’ (*Monadology* §§1-3). So understood, the Leibnizian world is grounded in non-extended simple substances, whose principal property is non-divisibility and thus, Leibniz inferred, non-extension.

From these basic characterizations of the individual or simple substance (what Leibniz called a ‘monad’ after the mid-1690s), he inferred a number of important properties. The individual substance or monad is a genuine unity that cannot be split, something explicit in the *Monadology* account, less so on the earlier account in the *Discourse*. Consequently, it can begin only by divine creation, and can end only with divine annihilation; it is naturally ungenerable and incorruptible. On both accounts, individual substances or monads are the sources of all their activity, and cannot be altered or changed by the direct action of others; it is in this sense that Leibniz said that ‘monads have no windows through which something can enter or leave’ (*Monadology* §7). In the *Discourse* he derives this from the fact that a substance contains within itself all of the grounds of all its properties; there is no need - and no room - for any external causality. In the *Monadology* it is derived directly from the fact that monads are non-extended. The apparent action of one substance on another must be analysed in terms of the relations between the internal states of the one and the internal states of the other (as discussed below). Finally, because of the relations that hold between one substance and another, Leibniz argued that each individual substance or monad reflects the entire world of which it is a part, a thesis closely connected with the hypothesis of pre-established harmony (also discussed below). Though all the individual substances reflect the same one world, they each reflect it from a different point of view, adding the perfection of variety to God’s creation (*Discourse* §§9, 15; *Monadology* §§4-7). This conception of harmony can be traced back to the Paris period and, perhaps, to Leibniz’s earliest writings on physics.

On Leibniz’s view, substances are distinguished from one another by their momentary perceptions, and by the appetitions, the internal source of a substance’s activity that lead from one perceptual state to another. In so far as a substance has such appetitions, ‘the present is pregnant with the future’ (*Monadology* §22). Since there can be no external influences, each monad is created by God with a kind of internal programme, as it were, which determines all of the states that it will take and the order in which it will take them. Although the Cartesian soul is an important model for the individual substance (Leibniz to de Volder, *c.*1699), there are significant differences.

While the momentary states are called perceptions, not all such perceptions are conscious. (Conscious perceptions are said to be 'apperceptions' in Leibniz's terminology, though because nature makes no leaps in this best of all possible worlds, there must be a continuous gradation between the unconscious and the conscious.) In scholastic thought, appetition is the general faculty that leads to change in a substance, of which will (or rational appetite) is a special case in rational souls. For Leibniz, too, not all appetition is rational. For these reasons, he distinguished carefully between rational souls, like ours, and monads with lesser degrees of consciousness and rationality - what he sometimes calls 'bare monads' (*Monadology* §§8-24).

5 Metaphysics: monad, body and corporeal substance

Much of Leibniz's attention was focused on the level of the individual substance or monad, the atom of nature and the building-block of his world, that which in some sense underlies the world of bodies. But in addition to the simple substances, Leibniz often also recognized complex substances, corporeal substances, particularly in the 1680s and 1690s. Corporeal substances are understood on analogy with the human being, a soul (itself an individual substance) united with an organic body. Leibniz often used Aristotelian language to characterize the corporeal substance, calling the soul its form, and the organic body its matter (see Aristotle §§8, 11). The organic body of a corporeal substance is itself made up of corporeal substances, each of which is a soul united to another, smaller organic body, in a sequence of tinier and tinier organisms that goes to infinity, a manifestation of the infinite variety in this best of all possible worlds that God created. Leibniz distinguished corporeal substances from corporeal aggregates, aggregates of animate corporeal substances whose unity is only mental, imposed by the mind, which perceives a group of substances together. While these corporeal substances are ultimately made up of non-extended individual substances, Leibniz's position (at least before 1704) seems to have been that these corporeal substances, as substances, are the genuine individuals whose reality grounds the aggregates that constitute inanimate bodies.

As discussed below, the soul of a corporeal substance is united to its body by virtue of pre-established harmony. However, by 1704, in response to criticism from René-Joseph de Tournemine, Leibniz came to think that this link does not produce genuine unity, and the notion of a corporeal substance becomes problematic for him. While he continued to assert that the physical world is made up of an infinite hierarchy of organisms, after this date he was not so sure that these organisms constitute genuine substances. (Nevertheless, Leibniz always thought that every monad has a body, and cannot exist without one, even if the monad together with its body does not constitute a genuine substance. Even in death the monad has a body, just a body radically smaller than the one it had had in 'life'.) The problem of constructing complex substances from monads led Leibniz in his correspondence with Des Bosses to explore the idea of a *vinculum substantiale*, or a substantial bond. While it is not clear that he ever really endorsed this idea, he does seem to have taken the problem of corporeal substance seriously in that dialogue.

However the issue of corporeal substance is treated, body had a kind of subordinate status for Leibniz. While corporeal substances may be genuine substances, genuinely individual and genuinely active, and thus genuinely real, they are still grounded in non-extended individual substances or monads. And inanimate bodies are inevitably phenomenal, whether the appearance resulting from a multitude of organic corporeal substances, or simply the appearance presented by an infinite multitude of non-extended substances. In this way, one can see Leibniz's philosophy as an inspiration for the distinction between the noumenal and the phenomenal worlds in Kant's philosophy. But in contrast to Kant, who claimed that we cannot know the noumenal world of the thing-in-itself, Leibniz is quite confident that he knows exactly how things are in themselves: they are monads (see Kant, I. §3).

6 Metaphysics: mind, body and harmony

A basic feature of Leibniz's metaphysics was his doctrine that everything reflects the entire world in which it exists. This harmony among things derives from God at creation, who adjusts the perceptions of individual substances or monads to one another in creating a world more perfect by virtue of its variety. And so, despite the fact that individual substances cannot communicate directly with one another, and thus have no real metaphysical causal relations with one another, yet there is an extended sense in which what happens in one substance can be considered the cause of what happens in another. Leibniz wrote: 'The action of one finite substance on another consists only in the increase of the degree of expression together with the diminution of the expression of the other, insofar as God requires them to accommodate themselves to one another' (*Discourse* §15; compare *Monadology* §52). God, in creating a given substance to perform a particular action at a given time, creates all

other substances in such a way as to reflect that action at that time. This is what might be called *physical* causality, as distinct from *metaphysical* causality which Leibniz denied among finite things.

While every monad or substance is related in some way to every other, there is a special relationship between the mind and the body of a living thing, such as the human being: ‘Although each created monad represents the whole universe, it more distinctly represents the body which is particularly affected by it, and whose entelechy it constitutes. And just as this body expresses the whole universe through the interconnection of all matter in the plenum (that is, space without empty place), the soul also represents the whole universe by representing this body, which belongs to it in a particular way’ (*Monadology* §62; compare *Discourse* §33). In this way, the mind is connected with the world by virtue of the special connection it has with the body; on Leibniz’s understanding of causality, mind and body can be the ‘physical’ causes of changes in one another.

So Leibniz solved to his satisfaction one of the central problems in seventeenth-century metaphysics: the interaction between mind and body. Because of the special harmony between mind and body, just when my body is in the state it would be in if it were pricked by a pin, my mind is programmed to have a sensation of pain. And just when my mind is in the state of willing my arm to raise, my body is in the physical state that would result in the raising of my arm, again not because of any direct causal connection (Leibniz to Arnauld, 28 November/8 December 1686 and 30 April 1687). For that reason, Leibniz wrote: ‘According to this system, bodies act as if there were no souls (though this is impossible); and souls act as if there were no bodies; and both act as if each influenced the other’ (*Monadology* §81). This is what he originally called the hypothesis of concomitance, but called the hypothesis of pre-established harmony when he published it for the first time in the *New system* (1695b).

The view is summarized in an analogy he often used. The mind and the body can be compared to two clocks that keep perfect agreement. One hypothesis to explain their agreement is that of natural influence, the hypothesis that there is some physical connection between the one clock and the other. This corresponds to Descartes’ view of mind-body interaction, where there is real causal influence. The second hypothesis is that someone watches over the two clocks and, by tinkering with them, always keeps them in agreement. This corresponds to the occasionalism of many of Descartes’ followers, in which mind-body causality is mediated by God who causes sensations in the mind on the occasion of an appropriate bodily state, and actions in the body on the occasion of the appropriate volition in the mind (see Occasionalism). Finally there is the hypothesis that the clocks are so well made that they will always remain in perfect agreement with one another. This corresponds to the hypothesis of pre-established harmony, which Leibniz thought to be the most defensible (Leibniz to Basnage de Beauval 3/13 January 1696).

Leibniz offered a number of arguments directly against occasionalism. He argued, for example, that there must be genuine activity in things themselves because a world of genuinely active things is more perfect than a world of things manipulated by God; indeed, Leibniz claimed, a world of inert things is just the Spinozistic world in which God is the only substance of which other things are modes (‘On nature itself’). He also argued that occasionalism posits perpetual miracles, in so far as God is called in to do that which goes beyond the power of things to do by their own nature (Leibniz to Arnauld, 30 April 1687). As noted below, the conception of the physical world that informs Leibniz’s dynamics is itself a direct challenge to occasionalism. Nevertheless, Leibniz did share at least one important doctrine with occasionalism: that finite substances have no real causal relations with one another. This doctrine may strike a modern reader as eccentric, but it would have been rather less so for a seventeenth-century reader.

Leibniz often presented the hypothesis of pre-established harmony as a solution to the problem of mind-body interaction. But, at the same time, it allowed Leibniz to reconcile the mechanistic conception of the world with a conception grounded in final causes. He wrote: ‘The soul follows its own laws and the body also follows its own; and they agree in virtue of the harmony pre-established between all substances.…Souls act according to the laws of final causes, through appetitions, ends, and means. Bodies act according to the laws of efficient causes or of motions. And these two kingdoms, that of efficient causes and that of final causes, are in harmony with each other’ (*Monadology* §§78-9). In more concrete terms, behaviour (raising one’s hand, for example) can be explained either in terms of a volition and the harmony God established between mind and body, or purely in terms of the laws of motion, as applied to the physical body. By pre-established harmony, these two explanations will always agree. In this way Leibniz managed to reconcile the dualism of Descartes with the stricter mechanism

of Hobbes; everything in the body can be explained in purely mechanistic terms, while, at the same time, Leibniz could also hold that human beings (and other living organisms) have souls which are the causes of much of their behaviour.

In addition to explaining the interaction between mind and body, when first introduced, Leibniz held that pre-established harmony also explains the union of mind and body, that which makes a single substance out of a mind and the collection of individual substances that constitutes its body (*Discourse* §33). In this way, pre-established harmony provided a central support for Leibniz's account of corporeal substance. Unfortunately, however, it proved inadequate to the task. In May 1703, René-Joseph de Tournemine pointed out that whatever resemblance one might suppose between two clocks, however justly their relations might be considered perfect, one can never say that the clocks are united just because the movements correspond with perfect symmetry. While it does not challenge pre-established harmony as an account of mind-body interaction, the argument is as simple as it is devastating against the somewhat different claim that pre-established harmony accounts for mind-body unity. In consequence, Leibniz came to question the place of complex corporeal substance in his philosophy, as discussed above (see Malebranche, N. §3; Occasionalism).

7 Metaphysics: necessity, contingency and freedom

Central to Leibniz's philosophy were a variety of problems concerning necessity, contingency and freedom, problems which arise in a variety of ways from a variety of sources. Spinoza stood behind many of Leibniz's worries. According to Spinoza, everything in the world is necessary and nothing is contingent, so that things could not be other than they are. Indeed, everything that is genuinely possible is actual and if something does not actually exist, it is because it could not. Everything follows from the divine nature, not by choice but by blind necessity. Furthermore, Spinoza argued, everything in the world is determined and what we take to be human freedom is just an illusion. We think that we are free because we are ignorant of the causes outside us that determine us to do what we do.

Other problems came from Leibniz's own views. Some came from Leibniz's principle in accordance with which 'when a proposition is not an identity, that is, when the predicate is not explicitly contained in the subject, it must be contained in it virtually' (*Discourse* §8). If every predicate true of an individual was part of its very concept, how could it fail to be necessary? A closely related problem followed from Leibniz's claim that every individual substance contains everything that can happen to it, past, present and future, which seems to entail that everything was determined from the beginning, and there is no room for the freedom of a creature. Here the problem concerns not necessity and contingency, but determinism and human freedom. Even if it were contingent that a certain creature has a certain built-in history, given that history, there does not appear to be room for freedom.

Leibniz offered a number of approaches to this problem in his writings. His basic response to the Spinozistic attacks on contingency is the claim that God *freely* chose the best of all possible worlds. He wrote in the early 1680s in an essay entitled *De libertate (On freedom)* 'God produces the best not by necessity but because he wills it' Leibniz [1680-2] 1989: 20). Yet, since God is perfect, it would seem that his nature necessarily determines his will to choose the best.

This led Leibniz directly to another account of contingency. In that same document, he continued by noting that 'things remain possible, even if God does not choose them'. That is, even if God *necessarily* created the best of all possible worlds (a concession Leibniz does not always make), unactualized possibles are still, in and of themselves, possible. The recognition of such unactualized possibles is what brought him back from the precipice of necessitarianism, so Leibniz wrote in another essay from the late 1680s (Leibniz 1989: 21). Elsewhere, he characterized those possibles that God chooses to create as necessary, but only *ex hypothesi*, on the hypothesis that God chose to create them. Though necessary in this limited sense, they are contingent in so far as their contraries are not self-contradictory (*Discourse* §13).

From time to time Leibniz used the kindred notion of compossibility. Two individuals are said to be compossible when they can be actualized at the same time, and are said not to be compossible when they cannot. In this way one can say that a possible world is a maximal set of compossible individuals. The notions of compossibility and incompossibility are not, however, logical notions, taken narrowly. Two individuals may fail to fit in the same possible world because they are logically in contradiction with one another (in a sense that must be specified), or

because they fail to harmonize with one another.

Leibniz sometimes also suggested that it is contingent that this particular world is the best of all possible worlds. So, even if God necessarily created the best of all possible worlds, it is still contingent that he creates *this* world. These arguments address the worries that derive from Spinoza's view that God necessarily gave rise to this world (see Spinoza, B. de §4). But, as noted above, there are other more Leibnizian worries to address as well. If in any true proposition the concept of the predicate must be contained in the concept of the subject, how can any truth fail to be necessary? Leibniz gave one kind of answer in the *Discourse on Metaphysics* (§13) where he simply asserts that there are two kinds of conceptual containment. While all predicates are contained in the concept of the subject, some are contained necessarily, and some contingently. But in some documents, probably from the late 1680s, he attempted a different solution. He noted first that in some cases we can demonstrate that the predicate is contained in the subject in a finite number of steps. However, in other cases this cannot be done. 'In contingent truths, even though the predicate is in the subject, this can never be demonstrated, nor can a proposition ever be reduced to an equality or to an identity, but the resolution proceeds to infinity' (Leibniz 1989: 96). To demonstrate a contingent truth, one must show that a given individual with a given property is one among an infinity of individuals in a possible world that is the best among an infinity of other possible worlds, something that cannot be shown in a finite number of steps.

Beyond the question of necessity is the issue of human freedom. Take an individual substance, which contains everything that has happened, is happening and will happen to it. Even if one can establish that the sequence of 'happenings' it contains is contingent, yet by virtue of containing all these happenings, it would seem not to be free to do anything other than what it does. Contingency is thus compatible with strict determinism, which is incompatible with human freedom.

Leibniz's solution was that while God may build certain actions into a given individual, he can build them in as *free* actions: 'God sees for all time that there will be a certain Judas whose notion or idea…contains this free and future action' (*Discourse* §30). God does make us with free will, and the ability to choose one thing over another. So, when he chooses to create a given individual with a given life-history, he will include the conditions that will lead that individual to choose one thing over another. But the actual choice is ours, and it is free, Leibniz argued. In this way, 'God inclines our soul without necessitating it' (*Discourse* §30). Furthermore, while we can choose other than the way we do, God in his omniscience can predict what we will actually choose, and build its consequences into our future programme. This divine foreknowledge does not change the character of the events themselves: 'God foresees things as they are and does not change their nature.…Thus they are assured but they are not necessary' (*Dialogue effectif sur la liberté de l'homme et sur l'origine du mal (An actual dialogue on human freedom and on the origin of evil)* [1695c] 1989: 112). Thus Leibniz had no worse problems on this score than does anyone who believes in divine omniscience.

Leibniz's doctrine did raise a knotty problem about the identity conditions for individuals, however. If all properties of a given individual are programmed in from the beginning, then though some may be contingent, and though some may be free, still, they define the individual as the particular individual that it is; were they different, then we would be dealing with another individual altogether, it would seem. From time to time Leibniz acknowledged that we might want to talk about what might have happened if Judas (*our* Judas, the Judas in *this* possible world) had not renounced Christ (*Leibniz-Arnauld Correspondence*, May 1686, (Leibniz 1875-90 vol. 2: 41-2); the specific example at issue there is not Judas, as in the *Discourse*, but Adam). But often Leibniz seemed quite willing to embrace a different view: 'But someone…will say, why is it that this man will assuredly commit this sin? The reply is easy: otherwise he would not be this man' (*Discourse* §30). In this way, given that every substance mirrors the entire world in which it finds itself, Leibniz often committed himself to the thesis that a person can belong to only *one* possible world.

8 Epistemology: ideas and sensation

Despite the fact that Leibniz is usually categorized as a continental rationalist, his main interest was not epistemological. At the same time, he did contribute to the discussions of his day on questions relating to ideas and knowledge.

In the *New Essays* (II.1.1), Leibniz defines an idea as follows: 'an idea is an immediate inner object [which]

expresses the nature or qualities of things'. He emphasizes that we can think that we have an idea when we do not really have one. So, for example, there can be no idea of a fastest motion because the notion is incoherent. But, he notes, 'At first glance we might seem to have the idea of a fastest motion, for we certainly understand what we say; but yet we certainly have no idea of impossible things'. Mistaking our comprehension of the phrase 'fastest motion' for having a genuine idea can lead us into contradiction in this case. But in other cases, for example in mathematics, where we often use symbols without fixing ideas to them, we often must work symbolically because of the complexity of working directly with ideas themselves. In this sense one can have thought and even reasoning when we do not have ideas in the proper sense. This observation is connected with a distinction Leibniz drew between real and nominal definitions. A nominal definition is a definition in which one can doubt whether or not the notion defined is genuinely possible; a real definition is one in which the possibility of the notion defined has been established. One can thus say that it is only of real definitions that one can be sure that they correspond to a genuine idea (*Meditations* [1684a] 1989: 25-6; *Discourse* §24).

Leibniz was a supporter of innate ideas in a number of senses. First of all, he argued that there are certain particular ideas that are innate to the mind, and do not or cannot come through the senses: 'The ideas of *being*, *possible*, and *same* are so thoroughly innate that they enter into all our thoughts and reasoning, and I regard them as essential to our minds' (*New Essays* I.3.3). He made a similar claim for other notions, such as infinity (*New Essays* II.17.3). In this connection he used his celebrated marble analogy in the preface to the *New Essays*. Ideas and truths are in the mind, he argued, just as the shape of Hercules might already be in the veins of a block of marble, making that shape more likely to emerge when the sculptor begins to hammer on it, even though considerable effort may be required to expose the shape: 'This is how ideas and truths are innate in us - as inclinations, dispositions, tendencies, or natural potentialities'.

Leibniz's metaphysics, however, committed him to a stronger position still, that *every* idea is innate, strictly speaking, since nothing can enter a mind from the outside. He wrote: 'The mind always expresses all its future thoughts and already thinks confusedly about everything it will ever think about distinctly. And nothing can be taught to us whose idea we do not already have in our mind' (*Discourse* §26). But even though all ideas are strictly innate, Leibniz could distinguish between the ideas of sensation that in a certain sense come to us from outside, and the ideas that do not and cannot do so. As with the explication of physical causality in the context of a view in which there can be no real metaphysical causality between finite things, Leibniz could say that 'we receive knowledge from the outside by way of the senses, because some external things contain or express more particularly the reasons that determine our soul to certain thoughts' (*Discourse* §27).

Sensations are distinguished from other notions not only by their causal origin (in Leibniz's somewhat extended sense), but also by the fact that they are confused, in contrast to the distinct notions one uses, say, in mathematics. A notion is distinct when one has 'marks and tests sufficient to distinguish a thing from all other similar' things; distinct notions include number, magnitude, shape and so on. A notion is confused 'when I cannot enumerate one by one marks sufficient for differentiating a thing from others, even though the thing does indeed have such marks and requisites into which its notion can be resolved'. In this sense 'colours, smells, tastes, and other particular objects of the senses' are confused (*Meditations* [1684a] 1989: 24). Indeed, they are the confused perception of the geometrical properties of bodies that, on the mechanist programme, ground the perception of sensible qualities. 'When we perceive colours or smells, we certainly have no perception other than that of shapes and of motions, though so very numerous and so very small that our mind cannot distinctly consider each individual one in this, its present state, and thus does not notice that its perception is composed of perceptions of minute shapes and motions alone' (*Meditations* [1684a] 1989: 27). Elsewhere Leibniz used the analogy of a wave to understand this phenomenon. When we hear the roar of the ocean, we are actually hearing just a large number of individual waves, lapping on the shore. But since we cannot distinguish the sounds each individual wave makes, we hear it as an undifferentiated roar. This is just the way the confused perception of the corpuscular microstructure of bodies results in our sensation of colour, taste and so on (*New Essays* 1704: preface). In this way Leibniz rejected the claim that the connection between a particular sensation and its mechanical cause is the result of a perfectly arbitrary divine decree; by the Principle of Sufficient Reason, there can be no such arbitrariness in the world (*New Essays* II.8.13 and following, IV.6.7). Thus, it would seem, the distinction between sensations and ideas of the intellect is not a matter of kind, but a matter of degree, degree of distinctness and confusion.

An important part of this account of sensation was Leibniz's doctrine of *petites perceptions* (minute perceptions).

Like Descartes, Leibniz believed that we think all the time. However, unlike Descartes, he denied that we are always conscious of what we think. He held that ‘at every moment there is in us an infinity of perceptions, unaccompanied by awareness or reflection; that is, of alterations in the soul itself, of which we are unaware because these impressions are either too minute and too numerous, or else too unvarying, so that they are not sufficiently distinctive on their own’ (*New Essays* preface). Though we do not apperceive (that is, consciously perceive) each of them individually, these unconscious perceptions have their effects on us. They are what underlie and explain sensation, as suggested earlier. Furthermore, they also have their effect on the conscious choices that we make (*New Essays* II.20.6).

Finally, Leibniz also had a clear position in the debate then raging in the intellectual world over Malebranche’s view that we see all things in God, that is, that ideas do not exist in finite minds, but only in the mind of God, where they are seen by finite intellects without actually being in them (see Malebranche, N. §2). Leibniz quite clearly rejected Malebranche’s view: ‘Even if we were to see everything in God, it would nevertheless be necessary that we also have our own ideas, that is, not little copies of God’s, as it were, but affections or modifications of our mind corresponding to that very thing we perceived in God’ (*Meditations* [1684a] 1989: 27; compare *Discourse* §29).

9 Epistemology: knowledge and probability

In a famous passage of the *Monadology* (§§31-2) Leibniz writes: ‘Our reasonings are based on *two great principles*, *that of contradiction*, in virtue of which we judge that which involves a contradiction to be false, and that which is opposed or contradictory to the false to be true, and *that of sufficient reason*, by virtue of which we consider that we can find no true or existent fact, no true assertion, without there being a sufficient reason why it is thus and not otherwise’. These two principles correspond to two different kinds of truths, ‘those of *reasoning* and those of *fact*’ *Monadology* §33).

A truth of reason can be known with certainty by a finite demonstration consisting of a finite number of steps containing simple ideas, definitions, axioms and postulates; these truths are necessary and can be known a priori. Sensation can give us particular instances of these truths, but can never attain the kind of universality one finds in necessary truths. As Leibniz wrote in the preface to the *New Essays*: ‘necessary truths, such as we find in pure mathematics and particularly in arithmetic and geometry, must have principles whose proof does not depend on instances nor, consequently, on the testimony of the senses, even though without the senses it would never occur to us to think of them’.

While Leibniz agreed with Descartes that such truths are innate, he distanced himself from Descartes’ appeal to clear and distinct perception. Against those who appeal to Descartes’ axiom that ‘whatever I clearly and distinctly perceive about a thing is true or is assertable of the thing in question’, Leibniz objected that ‘this axiom is useless unless we use criteria for the clear and distinct, criteria which we have made explicit’ (*Meditations* [1684a] 1989: 26-7). While Leibniz agreed with Descartes that we have an innate capacity to recognize these innate truths, as a practical matter, he preferred to constrain the mind by formal rules of logic, unlike Descartes, who rejected formal logic (see §10 below).

Since in all predications, the concept of the predicate is contained in the concept of the subject, all knowledge is in principle a priori; if we only had sufficient knowledge of the subject, we could see everything that is true of it, contained in its complete concept. But this is only possible for God. Humans, incapable of performing the analysis that will reveal the truth a priori must make appeal to the senses in order to discover truths of fact. In fact, Leibniz thought, ‘we are all mere Empirics in three fourths of our actions’ (*Monadology* §28).

Because of the importance of empirical knowledge, Leibniz called for a genuine logic of probability. The modern theory of probability was born in the 1650s with the correspondence between Pascal and Fermat, and then with Christiaan Huygens’ little treatise, *Tractus de ratiociniis in aleae ludo (Treatise on reasoning in games of chance)* (1657). The theory very quickly developed in the seventeenth century, as new practical applications were quickly found. But Leibniz was not satisfied that it had yet been applied to the most general question of all, the kind of reasoning we do about matters of fact on the basis of sensation when demonstration is impossible. And so, in the *New Essays* (IV.2.14) he called for a new science: ‘I maintain that *the study of the degrees of probability* would be very valuable and is still lacking, and that this is a serious shortcoming in our treatises on logic. For when one

cannot absolutely settle a question one could still establish the degree of likelihood on the evidence, and so one can judge rationally which side is the most plausible.…I suspect that the establishment of an *art of estimating likelihoods* would be more useful than a good proportion of our demonstrative sciences, and I have more than once contemplated it'. But even though Leibniz may have contemplated it, he himself never made a serious attempt to develop the logic of probability that he called for here. However, his call was heard by David Hume, who saw his *Treatise* as, in part, answering Leibniz's challenge.

10 Logic and language

From his youth, Leibniz dreamed of constructing a perfect, logical language, 'a certain alphabet of human thoughts that, through the combination of the letters of this alphabet and through the analysis of the words produced from them, all things can both be discovered and judged'. This programme, which Leibniz called the 'universal characteristic', gets its first expression in the very early work, *Dissertatio de arte combinatoria (Dissertation on the art of combinations)* (1666). But it is most fully developed later, from the mid-1670s into the 1680s.

Leibniz's programme had two parts. First, one must assign characteristic numbers to all concepts that show how they are built up out of simpler concepts. Leibniz tried a number of schemes for this, but one strategy was to assign simple concepts prime numbers, and then assign complex concepts the product of the characteristic numbers of its constituent simple concepts. The second part of the programme was then to find simple mechanical rules for the truth of propositions in terms of the characteristic numbers of their constituent concepts. Leibniz's fundamental rule in his Universal Characteristic was the principle discussed above in connection with his metaphysics: a predicate is true of a subject if and only if its concept is contained in the concept of the subject. If the concepts in question can be expressed numerically, then Leibniz thought that the rule can be given a mathematical form as well, and the truth of a proposition could be established by a simple arithmetical calculation. Leibniz's project in these writings was to show how this basic intuition about truth could be extended to propositions that are not in simple subject-predicate form. He also sought to extend the programme to formalize the validity of the standard inferences in Aristotelian logic. Even if he could not assign definite characteristic numbers to particular concepts, Leibniz tried to show that for certain configurations of premises and conclusions, if the premises are true (on his definition of truth), then so too must be the conclusion.

The programme was very ambitious; it if were successful, it would allow the truth or falsity of any proposition, necessary or contingent, to be determined by calculation alone. However, it soon dawned on Leibniz that the idea of finding all the conceptual dependencies necessary to express the contents of notions numerically was utopian in the extreme, particularly given the doctrine of infinite analysis of contingent truths Leibniz came to in the late 1680s. This realization still left in place the more modest programme of validating patterns of inference. But even this more modest programme turned out to be beyond Leibniz's ability to bring to completion, and after the early 1690s he seems to have given up trying to make it work, although he returned to it from time to time.

But even though this particular programme collapsed, the idea of formalism was quite basic to Leibniz's thought. Part of the reaction against the Aristotelian philosophy of the schools was an attack on formal logic. Descartes, Locke and others in the seventeenth century argued that we all have an innate ability to recognize truth, what was often called intuition, and that we should cultivate that capacity, and not waste our time learning formal rules. While Leibniz certainly agreed that we do have the innate capacity to grasp certain truths, he still thought that formalism is very important ((Leibniz to Elisabeth of Bohemia, 1678). Much of our reasoning is 'blind' or symbolic, Leibniz thought, conducted through the manipulation of symbols without having a direct hold on the ideas that underlie the symbols. For that reason we must have clear and unambiguous symbol systems, and strict rules for manipulating them (*Meditations*).

This view is evident in the papers on the Universal Characteristic. But it also underlies another project of the same period, the differential and integral calculus, one of Leibniz's greatest accomplishments, worked out by 1676 and made public from 1684. Though others before him had solved many of the particular problems his calculus could solve, problems relating to tangents, areas, volumes and so on, Leibniz invented a simple notation, still used in the calculus ('d' to represent the operation of differentiation, and ' ' to represent the operation of infinite summation (integration)), and worked out a collection of simple rules for applying these operations to equations of different kinds. In this way, Leibniz was able to produce simple algorithms for solving difficult geometrical problems 'blindly', by manipulating certain symbols in accordance with simple rules.

Another issue closely connected with Leibniz's logic is that of relations. In the *Primae veritates (First truths)* [1689] 1989: 32) Leibniz wrote: '*There are no purely extrinsic denominations* [that is, purely relational properties], denominations which have absolutely no foundation in the very thing denominated.…And consequently, whenever the denomination of a thing is changed, there must be a variation in the thing itself'. In this way, all relations must be, in some sense, grounded in the non-relational properties of things. But it is not clear that Leibniz held that relations had to be reducible to non-relational predicates of things. In one example he gives, he paraphrased 'Paris is the lover of Helen' by the following proposition: 'Paris loves, and by that very fact [*eo ipso*] Helen is loved'. While this certainly relates the relation '*A* loves *B*' to two propositions that have the form of simple subject-predicate propositions ('*A* loves' and '*B* is loved'), it should be noted that the predicates in question ('loves' and 'is loved') would seem to be implicitly relational; whether this is an accidental feature of the example Leibniz chose or a clue to Leibniz's views is a question of some dispute. Furthermore, it is important not to ignore that which connects the two propositions ('and by that very fact'), without which one cannot say that the two non-relational propositions capture the relation '*A* loves *B*' (Leibniz 1966: 14). Other texts suggest that individuals properly speaking have non-relational properties, and that the relations between things are something imposed by the mind onto the world: 'My judgement about relations is that paternity in David is one thing, sonship in Solomon another, but that the relation common to both is a merely mental thing whose basis is the modifications of the individuals' (Leibniz to Des Bosses, 21 April 1714). But in saying that the relations between individuals are 'merely mental', Leibniz does not necessarily mean to dismiss them. He wrote: 'God not only sees individual monads and the modifications of every monad whatsoever, but he also sees their relations, and in this consists the reality of relations and of truth' (Letter to Des Bosses, 5 February 1712).

In addition to formal languages, Leibniz was also keenly interested in the study of natural languages. Like many of his contemporaries, he was interested in the controversies over the question of the Adamic language, the language spoken in Eden and from which all modern languages supposedly derive. This, among other motivations, led him to the empirical study of different languages and the etymology of words (see Universal language).

11 Natural philosophy

Leibniz is read today largely for his philosophical writings. But in his day, he was, if anything, better known for his work in mathematics and natural philosophy. Like many of his contemporaries, Leibniz was a mechanist. Indeed, he was in a sense a much stricter mechanist than the Cartesians. Because of his doctrine of pre-established harmony (see §6 above), one can always give a purely mechanistic explanation of any physical phenomenon, even in humans, unlike in the Cartesian system, where causal interaction between mind and body, direct or occasional, can disrupt the laws governing the body. However, Leibniz's version of the mechanist programme departed significantly from other main versions of the programme of his day, particularly the Cartesian version.

Leibniz rejected the Cartesian analysis of body as extended substance (see §4 above). Instead, he argued that we must go to a deeper level of analysis, behind the extension of bodies to the substances that are the ultimate constituents of reality. Below the level of inanimate extension there are tiny organisms, souls joined to organic bodies which Leibniz, in at least one period of his thought, considered genuine corporeal substances. At a deeper level still there are the non-extended simple substances or monads that ground the reality of corporeal substances. On this view, the extended bodies of the Cartesian world are phenomena, aggregates of substances that are unified by virtue of being confusedly perceived together.

Leibniz also rejected Descartes' central law of nature. For Descartes, God conserves the same quantity of motion in the world, the size times the speed of bodies taken together (see Descartes, R. §11). But Leibniz argued that what is conserved is not bulk times speed, but bulk times the *square* of speed, mv^2, a quantity associated with what he called *vis viva* or living force. To defend this view, he used a cluster of a posteriori arguments which assumed the Galilean law of free-fall (the distance fallen is proportional to the square of the speed acquired in free-fall) together with the Principle of the Equality of Cause and Effect, in accordance with which there is always as much ability to do work in the cause as there is in the full effect. Leibniz showed that, on these assumptions, the Cartesian conservation law entails that the ability to do work can either be gained or lost in certain circumstances, whereas on the assumption of the conservation of mv^2, this does not happen. Leibniz used this strategy in the *Brevis demonstratio (Brief Demonstration of a Notable Error of Descartes)* (1686a), where he first published this result. In addition, he offered an a priori argument in which, arguing from certain abstract notions of motion, action

and effect, together with an intuitive principle of the conservation of effect, he reached the same conclusion (*Discourse* §17; *Dynamics* preliminary specimen). This challenge to Descartes' conservation law elicited numerous responses from the Cartesian community in what came to be called the *vis viva* controversy.

Leibniz saw the replacement of the conservation of the quantity of motion by the conservation of mv^2 as leading us to introduce into the world of physics something over and above the purely geometrical qualities of size, shape and motion that pertain to the extended substance of the Cartesians. This something is what he called force, the new science of which he named dynamics. While force can cause motion and is sometimes manifested in motion, Leibniz carefully distinguished the two. In emphasizing the distinction between force and motion, Leibniz was rejecting not only the Cartesian tradition, but his own early physics where, following Hobbes, he identified force with motion.

Leibniz recognized a variety of different kinds of forces in nature. At the most fundamental level, he distinguished between primitive and derivative forces, and between active and passive forces. Thus, in all, there are four basic kinds of force: primitive and derivative active force, and primitive and derivative passive force. Active force is of two sorts, living force (*vis viva*), which is associated with bodies actually in motion (a ball moving with a definite velocity), and dead force, which is associated with the instantaneous push from which actual motion results, as in gravitation or elasticity. Passive force, on the other hand, is the force that arises in reaction to the active force of another body. It also has two varieties, impenetrability (the force that prevents two bodies from occupying the same place at the same time) and resistance (the force that opposes new motion). The distinction between primitive and derivative force is quite different. Primitive force, active and passive, is the metaphysical ground of activity and passivity, that in a body by virtue of which it is capable of acting (doing work) or resisting. Derivative forces, for Leibniz, were particular states of activity and passivity that exist in a body at a particular time. In this way, primitive force is not a measurable quantity, but something in body that grounds the reality of the derivative forces, which are measurable quantities.

This notion of force was linked directly to Leibniz's notion of corporeal substance: 'Primitive active force, which Aristotle calls first entelechy and one commonly calls the form of a substance, is another natural principle which, together with matter or passive force, completes a corporeal substance' ('Note on Cartesian natural philosophy' [1702] 1989: 252). At least in the 1680s and 1690s, when Leibniz recognized corporeal substances, the primitive forces seem to have been the form and matter of the corporeal substances that ground the reality of the physical world. Derivative forces would then be interpreted as the momentary states of these corporeal substances. The position is somewhat different after Leibniz began to doubt the reality of corporeal substance (see §5 above). Then, he wrote, 'I relegate derivative forces to the phenomena, but I think that it is obvious that primitive forces can be nothing but the internal strivings of simple substances, strivings by means of which they pass from perception to perception in accordance with a certain law of their nature' (Leibniz to de Volder, 1704 or 1705). In this way, the dynamics can be regarded as another perspective on the same entities discussed in Leibniz's more metaphysical writings.

Leibniz held that these forces (or better, the motion that they cause) obey rigorous mathematical laws. These laws include the conservation of living force, mv^2, virtually equivalent to the modern law of the conservation of kinetic energy, and the conservation of bulk times the velocity (a vector quantity), mv, identical to the modern law of the conservation of momentum. (Because Leibniz's conservation of mv involved the directionality of the motion, it is distinct from the Cartesian conservation of quantity of motion, which Leibniz rejected.) While he disagreed with Descartes about the specific contents of the laws, he can be seen as advancing the Cartesian programme of building a physics grounded in mathematically expressible conservation laws. But even though Leibniz's laws are expressible in mathematical terms, they - like the forces that they govern - are grounded in certain metaphysical principles that are imposed on the world by the wisdom of God: 'Although the particular phenomena of nature can be explained mathematically or mechanically…nevertheless the general principles of corporeal nature and of mechanics itself are more metaphysical than geometrical' (*Discourse* §18).

One such general metaphysical principle was noted in connection with the establishment of Leibniz's conservation law, the Principle of the Equality of Cause and Effect. But there were others as well. Leibniz made frequent use of the Principle of Continuity, according to which nothing happens through a leap. Leibniz used this principle to refute Descartes' laws of impact, where small changes in the initial conditions (say the comparative sizes of the

bodies in question, or their motion) can result in radically different results. This principle was also used to refute atomism. If there are perfectly hard atoms, not made up of smaller separable parts, then in collision their motion would change instantaneously at the moment of impact. So, Leibniz concluded, there cannot be any such atoms in nature. Indeed, he used this argument to conclude that every body, no matter how small, is elastic. Leibniz also made appeal to the Principle of Plenitude to argue that there can be no vacuum or empty space in the world, since if God *can* create something consistent with his other creations, he *must* do so. Finally, as seen below, Leibniz used the Principle of Sufficient Reason in connection with his relativistic account of space and time.

The very fact that the world is the product of divine wisdom allowed Leibniz to appeal to final causes in his physics. This differentiates him from both Descartes and Spinoza, both of whom rejected final causes. Leibniz agreed with both that everything in nature can be explained through efficient cause alone - that is, through the laws of motion alone. But often, particularly in optics, it is much easier to solve problems by appealing to God's wisdom, and discovering the way in which a most perfect being would have created his universe (*Discourse* §22; *Specimen of dynamics* 1695a: part I). However, the appeal to final cause only supplements the understanding of nature by efficient causes, and does not replace it. It is another manifestation of divine harmony that the explanations by efficient causes and by final causes always coincides: 'In general we must hold that everything in the world can be explained in two ways: through the kingdom of power, that is, through efficient causes, and through the kingdom of wisdom, that is, through, final causes.…These two kingdoms everywhere interpenetrate each other…so that the greatest obtains in the kingdom of power at the same time as the best in the kingdom of wisdom' ((*Specimen of dynamics* [1695a: part I] 1989: 126-7).

So far we have been discussing Leibniz's work in relation to that of other mechanists, particularly those of the Cartesian school. But it is also important to understand Leibniz's relations with another contemporary and often bitter rival, Isaac Newton.

In opposition to Newton, who held an absolutist conception of place and space, Leibniz argued that space is 'only relations or order or orders of coexistence, both for the actually existing thing and for the possible thing one can put in its place' (*Remarks on Foucher* [1696] 1989: 146). If Newton were right, Leibniz argued, and there was absolute space, then God could create a world in which what is currently east and west are exactly reversed, for example. But if so, by the Principle of Sufficient Reason, then God could have no reason to create one such world over another. Given that he did, he cannot have been faced with such a choice. Leibniz concludes that the two purported Newtonian worlds are really just one world, a world in which space is just constituted by the relations between things (Leibniz to Clarke, 3rd paper §5). Newton's absolutist account of space was supposed to ground an absolutist account of motion as well. For Newton, motion was the change of place of a body with respect to absolute space. Leibniz rejected this too, arguing that motion is a completely relativistic notion, a matter of the relation between bodies over time and that alone (*Specimen of dynamics* part I; Leibniz to Huygens, 12/22 June 1694).

Leibniz also rejected Newton's theory of universal gravitation. He read Newton as holding that gravity is an essential property of matter as such, and he was appalled. For Leibniz, all change in body had to happen through the intermediary of contact and collision; the idea of action at a distance that seemed to underlie Newton's theory of universal gravitation was an intellectual disaster, a treasonable abandonment of the new mechanical philosophy and a return to the worst abuses of the schoolmen. Leibniz, whose early mechanism seemed so radical at the time, could not adjust to the new Newtonian philosophy, soon to take over the intellectual world (see Clarke, S.; Newton, I.).

While the emphasis here has been on the aspects of Leibniz's work in physics most relevant to his philosophical programme, he was much more widely interested in the natural world. He left notes on engineering problems, on chemistry, on geology and on curious observations in natural history including the report of a talking dog, and a goat with an odd hairstyle.

12 Ethics and political thought

Although Leibniz's ethical and political writings are not widely read today, they constitute an important part of his corpus, unsurprising, given Leibniz's own involvement in politics. Leibniz's ethical and political thought, squarely within the natural law tradition, was based on the notions of justice, charity and virtue (see Natural law). Leibniz

wrote: ‘Charity is a universal benevolence, and benevolence the habit of loving or of willing the good. Love then signifies rejoicing in the happiness of another, or, what is the same thing, converting the happiness of another into one’s own’ *Codex Iuris Gentium Diplomaticus (The diplomatic code of the law of nations)* [1693: introduction] 1988: 171). In a note on felicity (Leibniz [*c*.1694-8] 1988: 83-4), he connected justice, wisdom, and virtue to charity: ‘Virtue is the habit of acting according to wisdom.…Wisdom is the science of felicity, [and] is what must be studied above all things.…To love is to find pleasure in the perfection of another. Justice is charity or a habit of loving conformed to wisdom. Thus when one is inclined to justice, one tries to procure good for everybody, so far as one can, reasonably, but in proportion to the needs and merits of each’.

For Leibniz, human justice is the same as God’s justice, though, of course, less perfect. Leibniz wrote in the *Monita quaedam ad S. Puffendorfii principia (Observations on the Principles of Pufendorf)* ([1706] 1988: 69): ‘In the science of law…it is best to derive human justice, as from a spring, from the divine, to make it complete. Surely the idea of the just, no less than that of the true and the good, relates to God, and above all to God, who is the measure of all things’. Similarly, Leibniz wrote in *Méditation sur la notion commune de la justice (Meditation on the common concept of justice)* ([1702-3] 1988: 60) that ‘as soon as [the concept of justice] is founded on God or on the imitation of God, it becomes universal justice, and contains all the virtues’.

In so far as charity is defined in terms of universal love and benevolence, justice is something quite distinct from power. This is true even for God. ‘Justice, indeed, would not be an essential attribute of God, if He himself established justice and law by His free will’. In this sense, God is as bound by the eternal laws of justice as he is bound by truths of reason: ‘Justice follows certain rules of equality and of proportion [which are] no less founded in the immutable nature of things, and in the divine ideas, than are the principles of arithmetic and of geometry’ (*Observations on Pufendorf* [1706] 1988: 69). (Here, perhaps is the origin of the theodicy problem for Leibniz: if God is bound by the same ideal of justice that binds us, then we must show how the works of the all-perfect creator can be seen to conform to that ideal.) So, too, are we bound by a standard of justice that exists independently of our wills.

Leibniz recognized three degrees of justice. The lowest, a minimal sort of justice, is simply not to harm others. The second degree is to give each their due, what it is that is owed to them. The highest, though, is to behave with genuine beneficence toward others, and to do that which will promote their happiness; this is what Leibniz calls piety (Leibniz to Coste, 4 July 1706: appendix).

Leibniz’s conception of justice as the charity of the wise also placed virtue and obligation outside of the scope of a contract. For Hobbes, for example, the notion of justice arises from a contract that we make with one another in forming a society, and the notion of justice has no applicability outside that framework. Commenting on Shaftesbury in 1712, Leibniz wrote: ‘Our illustrious author refutes with reason…those who believe that there is no obligation at all in the state of nature, and outside government; for obligations by pacts having to form the right of government itself, according to the author of these principles, it is manifest that the obligation is anterior to the government which it must form’ (Leibniz 1988: 196). Indeed, he noted, there are societies, among the native Americans for example, in which the sovereign thought necessary by Hobbes is altogether absent: ‘entire peoples can be without magistrates and without quarrels, and…as a result men are neither taken far enough by their natural goodness nor forced by their wickedness to provide themselves with a government and to renounce their liberty’. In people sufficiently wise, then, justice and charity are sufficient to hold society together, without the need of a contract.

But Leibniz was a practical politician, as well as a theorist of politics. He generally worked for a Europe unified under the leadership of a unified church, a Christian Europe in which there are no conflicts between different Christian states. This, in part, is what was behind his plan for the reunification of the Catholics and the Protestants. It was also behind his attempt, as early as 1671, to persuade the French to attack Egypt, a non-Christian country, rather than to invade the Netherlands. In practice, however, Leibniz was an opponent of French expansionism under Louis XIV (as much as he was an admirer of French culture), and a supporter of a union of Protestant countries in Northern Europe (his *Mars Christianissimus* (1684b) was a brilliant satire directed against Louis XIV’s foreign policy). He was also an active participant in the successful campaign in support of the claim of the House of Hanover for the throne of England.

13 The Leibnizian tradition

It is important to remember when considering Leibniz's influence that much of what we now know of Leibniz's writings was unknown to his readers for many years after his death. The full dimensions of Leibniz's thought emerged only slowly, as new texts came to light. Indeed, there is still no complete edition of his work.

At the time of his death, and in the decade afterwards, only a small selection of Leibniz's texts was available. There were a fair number of publications in mathematics and physics, some legal writings and some documents collected in connection with his unfinished history of the house of Hanover. In philosophy, however, there were only a few essays. During his lifetime, Leibniz had published *Meditations on Knowledge, Truth, and Ideas* (1684a), the *New System* (1695b), *On Nature Itself* (1698) and the *Theodicy* (1710). The Leibniz-Clarke correspondence was published soon after his death, and a Latin version of the *Monadology* appeared in 1721. On the other hand, the *New Essays* did not appear until 1765, and works that we now consider central, such as the *Discourse on metaphysics*, did not appear until 1846. Many of his philosophical writings and correspondence had to await the monumental edition of C.I. Gerhardt, which appeared between 1875 and 1890. Many texts have yet to appear.

Despite the relative paucity of his available writings, Leibniz was much read and debated in the eighteenth century. One of his early supporters was the German professor Christian Wolff who had corresponded with Leibniz during his life. He composed numerous volumes expounding a Leibnizian philosophy in an ordered and orderly way. Wolff's systematic philosophy made it ideal for the academy, and his ideas were widely influential. But there were opponents, particularly a group of pietist theologians at the University of Halle, but others as well, including Maupertuis, Crusius, Condillac and, most famously, Voltaire, who made Leibniz into the comical Dr Pangloss of his *Candide*. Kant received his philosophical education in the atmosphere of this debate between the Leibnizians and the anti-Leibnizians in the German intellectual world. His philosophy, both pre-critical and critical, shows the marks of his knowledge of Leibniz's writings.

DANIEL GARBER

List of works

Many of Leibniz's writings, including some of the most important of them, remained unpublished during his lifetime. As a consequence, some of them can be dated only approximately.

Leibniz, G.W. (1768) *Leibnitii opera omnia (The complete works of Leibniz)*, ed. L. Dutens, Geneva, 6 vols; repr. Hildesheim: Olms, 1989.(Contains a wide range of Leibniz's papers, both inside and outside philosophy, many of which have not been reprinted since the eighteenth century. It gives the best sense of what Leibniz meant to his contemporaries.)

Leibniz, G.W. (1849-63) *Mathematische Schriften (Mathematical writings)*, ed. C.I. Gerhardt, Berlin and Halle: A. Asher & comp. and H.W. Schmidt, 7 vols; repr. Hildesheim: Olms, 1962.(Still the most complete collection of Leibniz's papers and letters in mathematics and physics, in the original languages, many of which are directly connected to his more philosophical interests.)

Leibniz, G.W. (1875-90) *Die philosophischen Schriften (Philosophical writings)*, ed. C.I. Gerhardt, Berlin: Weidmannsche Buchhandlung, 7 vols; repr. Hildesheim: Olms, 1978.(Still the most complete collection of Leibniz's philosophical papers and letters in the original languages.)

Leibniz, G.W. (1923-) *Sämtliche Schriften und Briefe (Collected writings and letters)*, ed. Deutsche Akademie der Wissenschaften (before 1945, Preussische), Berlin: Akademie Verlag.(This is to be the new complete critical edition of Leibniz's writings in the original languages, edited to the highest standards. Currently still in its early stages, it must be supplemented by earlier editions. In recent years it has been supplemented by a 'Vorausedition', giving pre-prints of editorial work in progress.)

Leibniz, G.W. (1666) *Dissertatio de arte combinatoria (Dissertation on the art of combinations)*, Leipzig; repr. in *Die philosophischen Schriften*, vol. 4; partial trans. L.E. Loemker in *Philosophical Papers and Letters*, Dordrecht: Reidel, 1969. (Leibniz's first important publication, concerning the theory of mathematical combinations, together with various philosophical digressions. It also contains a suggestion of his later concern with a universal language.)

Leibniz, G.W. (*c*.1680-2) *De libertate (On freedom)*, in *Textes inédites*, vol. 1, ed. G. Grua, Paris: Presses Universitaires de France, 1948; trans. R. Ariew and D. Garber in *Leibniz: Philosophical Essays*, Indianapolis,

IN and Cambridge, MA: Hackett Publishing Company, 1989.(Interesting essay on human and divine freedom and contingency, unpublished in Leibniz's lifetime.)

Leibniz, G.W. (1684a) 'Meditationes de cognitione, veritate et ideis' (Meditations on knowledge, truth and ideas), *Acta Eruditorum* (November 1684): 537-42; repr. in *Leibnitii opera omnia*, vol. 4; trans. R. Ariew and D. Garber in *Leibniz: Philosophical Essays*, Indianapolis, IN and Cambridge, MA: Hackett Publishing Company, 1989. (Important explanation of Leibniz's views on concepts, truth and knowledge.)

Leibniz, G.W. (1684b) *Mars Christianissimus (Most Christian War-God)*, Cologne; trans. P. Riley in *Leibniz: Political Writings*, Cambridge: Cambridge University Press, 1988. (A satire on the diplomatic policies of Louis XIV.)

Leibniz, G.W. (1686a) 'Brevis Demonstratio erroris memorabilis Cartesii' (Brief demonstration of a notable error of Descartes), *Acta Eruditorum* (March 1686): 161-3; repr. in *Mathematische Schriften*, vol. 6; trans. L.E. Loemker in *Philosophical Papers and Letters*, Dordrecht: Reidel, 1969.(A refutation of Descartes' law of the conservation of quantity of motion in physics.)

Leibniz, G.W. (1686b) *Discours de métaphysique (Discourse on metaphysics)*, 1846; ed. H. Lestienne, Paris: Alcan, 1907; trans. R. Ariew and D. Garber in *Leibniz: Philosophical Essays*, Indianapolis, IN and Cambridge, MA: Hackett Publishing Company, 1989.(Unpublished in Leibniz's time, this is a central text in which Leibniz gives an exposition of some central elements of his metaphysics as of 1686.)

Leibniz, G.W. (1686-90) *The Leibniz-Arnauld Correspondence; repr. with related letters and documents in Die philosophischen Schriften*, vol. 2: Weidmannsche Buchhandlung, 1875-90, 1956; trans. and ed. H.T. Mason, Manchester: Manchester University Press, 1967.(Very important series of letters exchanged between Leibniz and the Cartesian philosopher Antoine Arnauld just as Leibniz was setting out his mature philosophy, providing a kind of commentary on themes developed in the *Discourse*. Although unpublished in his lifetime, Leibniz probably intended it for publication.)

Leibniz, G.W. (*c.*1689a) *De libertate (On Freedom)*, in *Textes inédites*, vol. 1, ed. G. Grua, Paris: Presses Universitaires de France, 1948; trans. R. Ariew and D. Garber in *Leibniz: Philosophical Essays*, Indianapolis, IN and Cambridge, MA: Hackett Publishing Company, 1989.(Another essay on contingency and freedom, unpublished in Leibniz's lifetime, which makes use of his infinite analysis account of contingency.)

Leibniz, G.W. (1689b) *Primae veritates (First truths)*; repr. in *Opuscules et fragments inédits*, 1903; trans. R. Ariew and D. Garber in *Leibniz: Philosophical Essays*, Indianapolis, IN and Cambridge, MA: Hackett Publishing Company, 1989. (An important, unpublished summary of Leibniz's metaphysics as of the 1680s. Originally thought to have preceded the 1686 composition of the *Discourse*, it is now firmly dated at 1689.)

Leibniz, G.W. (1690) *Dynamica (Dynamics)*, in *Mathematische Schriften*, vol. 6; partial trans. R. Ariew and D. Garber in *Leibniz: Philosophical Essays*, Indianapolis, IN and Cambridge, MA: Hackett Publishing Company, 1989.(Unpublished in Leibniz's time, this is a systematic exposition of Leibniz's physics. Apart from the translation of the preliminary discourse in Ariew and Garber, the bulk of this work has not been translated from the original Latin.)

Leibniz, G.W. (1692) *Protogaea*, 1749; French trans, ed. B. de Saint-Germain and J.-M. Barrande, Toulouse: Presses Universitaires du Mirail, 1993.(A treatise on geology and the early days of the earth, written as the first part of Leibniz's history of the House of Hanover.)

Leibniz, G.W. (1693) *Codex Iuris Gentium Diplomaticus (The diplomatic code of the law of nations)*, Hanover; partial trans. P. Riley in *Leibniz: Political Writings*, Cambridge: Cambridge University Press, 1988.(Collection of diplomatic papers, with a long introduction on political philosophy.)

Leibniz, G.W. (*c.*1694-8) *La félicité (Felicity)*; repr. in *Textes inédites*, vol. 1; trans. P. Riley in *Leibniz: Political Writings*, Cambridge: Cambridge University Press, 1988. (Important but unpublished note from the 1690s in which Leibniz discusses his theory of justice as the charity of the wise man.)

Leibniz, G.W. (1695a) *Specimen dynamicum (A specimen of dynamics)*, Part I, *Acta Eruditorum* (April 1695); repr. (Parts I and II) in *Mathematische Schriften*, vol. 4; trans. R. Ariew and D. Garber in *Leibniz: Philosophical Essays*, Indianapolis, IN and Cambridge, MA: Hackett Publishing Company, 1989.(Important work that links the technical physics of the *Dynamica* with more philosophical themes. Only Part I was published during Leibniz's life.)

Leibniz, G.W. (1695b) 'Système nouveau de la nature et de la communication des substances' (New system of the nature and the communication of substances), *Journal des Sçavans* (27 June 1695): 294-300; repr. in *Die philosophischen Schriften*, vol. 4; trans. R. Ariew and D. Garber in *Leibniz: Philosophical Essays*, Indianapolis, IN and Cambridge, MA: Hackett Publishing Company, 1989.(A popular presentation of Leibniz's metaphysics, featuring the first public presentation of the hypothesis of pre-established harmony.)

Leibniz, G.W. (1695c) *Dialogue effectif sur la liberté de l'homme et sur l'origine du mal (An actual dialogue on*

human freedom and on the origin of evil); repr. in *Textes inédites*, vol. 1; trans. R. Ariew and D. Garber in *Leibniz: Philosophical Essays*, Indianapolis, IN and Cambridge, MA: Hackett Publishing Company, 1989.(This seems to be a record of a dialogue that actually took place between Leibniz and Baron Dobrzensky, counsellor of state and war of Brandenburg.)

Leibniz, G.W. (1696) 'Remarques sur les Objections de M. Foucher' (Remarks on the objections of M. Foucher), *Histoire des ouvrages des Savans* (February 1696): 274-6; repr. in *Die philosophischen Schriften*, vol. 4; trans. R. Ariew and D. Garber in *Leibniz: Philosophical Essays*, Indianapolis, IN and Cambridge, MA: Hackett Publishing Company, 1989.(An excellent but brief account of Leibniz's view on the problem of the continuum.)

Leibniz, G.W. (1697) *De rerum originatione radicali (On the ultimate origination of things)*; repr. in *Die philosophischen Schriften*, vol. 7; trans. R. Ariew and D. Garber in *Leibniz: Philosophical Essays*, Indianapolis, IN and Cambridge, MA: Hackett Publishing Company, 1989.(This important brief essay on creation and contingency remained unpublished until the nineteenth century.)

Leibniz, G.W. (1698) 'De ipsa natura' (On nature itself), *Acta Eruditorum* (September 1698): 427-40; repr. in *Die philosophischen Schriften*, vol. 4; trans. R. Ariew and D. Garber in *Leibniz: Philosophical Essays*, Indianapolis, IN and Cambridge, MA: Hackett Publishing Company, 1989.(Significant essay on the importance of introducing genuinely active individuals into the world, against the Cartesian position that bodies are bare, extended substances.)

Leibniz, G.W. (1702) 'Note on Cartesian natural philosophy'; repr. in *Die philosophischen Schriften*, vol. 4; trans. R. Ariew and D. Garber in *Leibniz: Philosophical Essays*, Indianapolis, IN and Cambridge, MA: Hackett Publishing Company, 1989.(Untitled by Leibniz and not published in his lifetime, this is an important summary of the philosophical aspects of Leibniz's dynamics.)

Leibniz, G.W. (1702-3) *Méditation sur la notion commune de la justice (Meditation on the common concept of justice)*; trans. P. Riley in *Leibniz: Political Writings*, Cambridge: Cambridge University Press, 1988. (Unpublished in Leibniz's lifetime, this is an important source for understanding his political philosophy.)

Leibniz, G.W. (1704) *Nouveau essais sur l'entendement humain (New essays in human understanding)*, 1765; repr. in *Sämtliche Schriften und Briefe*, series 6, vol. 6; trans. P. Remnant and J. Bennett as *New Essays on Human Understanding*, Cambridge: Cambridge University Press, 1981.(Unpublished in Leibniz's lifetime, this is a point-by-point discussion of Locke's *Essay Concerning Human Understanding*.)

Leibniz, G.W. (1706) *Monita quaedam ad S. Pufendorfii principia (Observations on the Principles of Pufendorf)*; repr. in *Leibnitii opera omnia*, vol. 4, part 3; trans. P. Riley in *Leibniz: Political Writings*, Cambridge: Cambridge University Press, 1988. (Unpublished in his lifetime, these are Leibniz's comments on the political thought of Samuel Pufendorf, the seventeenth-century jurist.)

Leibniz, G.W. (1710) *Essais de Théodicée (Essays on Theodicy)*, Amsterdam; trans. E.M. Huggard as *Theodicy*, La Salle, IL: Open Court, 1985.(A treatise in which Leibniz attempts to justify the ways of God to man. Much of the work is a response to the writings of Pierre Bayle.)

Leibniz, G.W. (1712) *Jugement sur les oeuvres de Mylord Shaftesbury (Judgment of the works of the Earl of Shaftesbury)*; repr. in *Leibnitii opera omnia*, vol. 5; trans. P. Riley in *Leibniz: Political Writings*, Cambridge: Cambridge University Press, 1988. (Unpublished in Leibniz's lifetime, this is a free-ranging discussion of Shaftesbury's work that includes much of interest for Leibniz's political thought.)

Leibniz, G.W. (1714a) *Monadologie*, 1721; repr. in *Die philosophischen Schriften*, vol. 6; critical edn, ed. A. Robinet, *Principes de la nature et de la grâce…et Principes de la philosophie ou monadologie*, Paris: PUF, 1986; trans. R. Ariew and D. Garber as *Monadology* in *Leibniz: Philosophical Essays*, Indianapolis, IN and Cambridge, MA: Hackett Publishing Company, 1989.(Central text, not published during his lifetime, in which Leibniz gives a summary of his metaphysics at the end of his life.)

Leibniz, G.W. (1714b) 'Principes de la nature et de la grâce' (Principles of nature and grace), *Acta Eruditorum* (September 1698): 427-40; repr. in *Die philosophischen Schriften*, vol. 6; critical edn, ed. A. Robinet, *Principes de la nature et de la grâce…et Principes de la philosophie ou monadologie*, Paris: PUF, 1986; trans. R. Ariew and D. Garber in *Leibniz: Philosophical Essays*, Indianapolis, IN and Cambridge, MA: Hackett Publishing Company, 1989.(Another late summary of Leibniz's metaphysics, a companion to the *Monadology*, also not published during his lifetime.)

Leibniz, G.W. (1714c) 'De ipsa natura' (On nature itself), *Acta Eruditorum* (September 1698): 427-40; repr. in *Die philosophischen Schriften*, vol. 4; trans. R. Ariew and D. Garber in *Leibniz: Philosophical Essays*, Indianapolis, IN and Cambridge, MA: Hackett Publishing Company, 1989.(Significant essay on the importance of introducing genuinely active individuals into the world, against the Cartesian position that bodies are bare, extended substances.)

Leibniz, G.W. (1715-16) *The Leibniz-Clarke Correspondence*, 1717; trans. and ed. H.G. Alexander, Manchester: Manchester University Press, 1956.(The Alexander edition has a useful introduction and notes to the translation of the exchange.)

Leibniz, G.W. (1903) *Opuscules et fragments inédits (Unpublished short works and fragments)*, ed. L. Couturat, Paris: Alcan; repr. Hildesheim: Olms, 1966.(The first publication of many of Leibniz's papers on logic, language, and related areas of metaphysics, published in the original languages; this collection shaped earlier twentieth-century views of Leibniz's programme as driven by his logic.)

Leibniz, G.W. (1948) *Textes inédites d'après les manuscrits de la bibliothèque provinciale de Hanovre (Unpublished texts, following the manuscripts in the provincial library at Hanover)*, ed. G. Grua, Paris: Presses Universitaires de France, 2 vols; repr. New York: Garland, 1985.(The first publication, in the original languages, of a valuable selection of writings concentrating on ethical, political and theological subjects.)

Leibniz, G.W. (1966) *Logical Papers*, ed. and trans. G.H.R. Parkinson, Oxford: Oxford University Press.(A collection of Leibniz's logical papers, translated into English, with an extensive introduction.)

Leibniz, G.W. (1969) *Philosophical Papers and Letters*, ed. and trans. L.E. Loemker, Dordrecht: Reidel.(The most extensive collection of Leibniz's writings in English, with a long introduction and useful notes.)

Leibniz, G.W. (1973) *Philosophical Writings*, ed. G.H.R. Parkinson, trans. M. Morris and G.H.R. Parkinson, London: Dent; Totowa, NJ: Rowman & Littlefield.(A useful collection in English translation.)

Leibniz, G.W. (1988) *Leibniz: Political Writings*, ed. and trans. P. Riley, Cambridge: Cambridge University Press, 2nd edn.(An excellent collection of Leibniz's moral and political writings, with a useful introduction.)

Leibniz, G.W. (1989) *Leibniz: Philosophical Essays*, ed. and trans. R. Ariew and D. Garber, Indianapolis, IN and Cambridge, MA: Hackett Publishing Company.(A widely available translation of a selection of Leibniz's most important philosophical texts.)

Leibowitz, Yeshayahu (1903-94)

Unlike the major intellectual currents that shaped religious thought in the modern world, Leibowitz's thought is deeply anchored in the Israeli context. Both as philosopher and activist, Leibowitz lived and articulated the paradoxes of modern Israel where he lived and was best known. His reputation as a Socratic gadfly to the establishment reflected his ongoing critique of both Israeli society in the light of Judaism, and Judaism in the light of the revolutionary implications of the creation of the State of Israel.

On the one hand, he was a Jewish patriot, a fighter for Jewish independence from all forms of foreign rule; on the other hand, he was a harsh, relentless critic of national and political expressions of chauvinism in the Israeli establishment. A strictly observant Jew, Leibowitz had less impact on traditional religious Jews than on secular Israelis. His central message is that what makes Jews distinctive as a group is neither their theology nor their Bible, but the system of law with which they regulate their lives. Judaism is a communal concept, and there is no point in religious Jews ignoring the State of Israel, or expecting others to bear their civil burdens for them. Religious law has to be reconciled with life in the political reality of the state, and this necessitates changing those attitudes to the law which reflect the historical conditions of life in exile.

1 The challenge to Judaism

According to Leibowitz, the essential subject of Judaism is not the individual but community. Its primary concern is not with personal sin and finitude, but with community and its commitment to serve God. He argued that the essential factor which distinguishes Jews from other nations is not theology or the Bible, but *halakhah* Jewish law (see Halakhah). The laws governing what Jews eat, when they work and how they worship, constitute the uniqueness of the Jewish nation. The primacy of *halakhah* in Judaism is less a value judgment than an empirical fact of history. The relative tolerance of Jewish communities for a variety of theological opinions stands in sharp contrast to their intolerance to forms of practice that deviate from *halakhah*. Jews share a distinctive form of religious life, regardless of their divergent or even contradictory conceptions of God.

Jewish life remained broadly characterizable in terms such as these until the beginning of the Emancipation at the end of the eighteenth century. But emancipation led to the growth of movements to modify or abandon parts of *halakhah* while preserving the synagogue as a place of worship. It also led to the emergence of secular Zionism. Leibowitz argues that the secular option, which claims continuity with the Jewish people yet abandons *halakhah* and the worship of God as defining features of Jewish identity is a falsification of the facts of Jewish history.

The question of the relationship between religion and state is connected to the larger theological issue of the religious significance of historical events. To Leibowitz, God cannot be understood in personalistic theistic terms. All attempts at describing God from a human perspective are tantamount to idolatry. In this respect, Leibowitz's position is similar to Maimonides' negative theology (see Maimonides, M.). One might characterize his analysis of religious language as prescriptive rather than descriptive. One cannot talk to or about God; one can only act in the presence of God. Religious language is informed by and must be limited to the worship of God. God is not to be invoked to justify ethical or political judgments; for such usage makes God subservient to human needs. Paradigmatic for Leibowitz's understanding of Judaism is the binding of Isaac, where Abraham is ready to sacrifice his only son (representing history, the self, the human) in unconditional obedience to God's will. The Jewish model for Leibowitz's religious orientation, however, is not the personalistic theistic framework of the Bible, but the religious ethos and communal framework of the talmudic tradition. The revelatory movement of God in history, as represented in the Bible, is replaced by the worshipping movement of the Jews towards God, which the talmudic tradition embodies. Leibowitz distinguished Judaism from Christianity in terms of the latter's promise of personal salvation and liberation from finitude and sin. In Judaism, the world as it is - with the promise of redemption - expresses the will and wisdom of God. All events mirror God's power, just as all nature manifests God's wisdom. No particular event can be singularly endowed with religious meaning, so there is no theology of history. Neither the rebirth of Israel nor the tragic events of the twentieth century have instrinsic religious meaning. Similarly, holiness is not something intrinsic to things, either animate or inanimate. Holiness results solely from human action in the service of God; it is a *halakhic* and not an ontological category. Judaism as represented concretely in *halakhah* is a constant effort and striving to realize God's commands in the world.

2 Zionism and the critique of religious Zionists

Unlike the religious conservatism of the ultra-Orthodox who relegate the legitimacy of Jewish political autonomy to an eschatological future, Leibowitz participated actively in the political struggle to re-establish an autonomous, self-governing Jewish community. While believing that nothing in the past fifteen hundred years could be compared to this heroic decision of Jews to alter their political destiny, he realized that the majority of these Jews were not motivated by a religious purpose.

Leibowitz defined Zionism as the natural expression of a national community seeking to cast off political subjugation and subservience to others. This collective impulse is in itself legitimate and healthy; it has no need of religious justification (see Zionism).

Nevertheless, religious Zionists adopted, or rather, co-opted this nationalist impulse by redefining the State of Israel's natural - albeit remarkable - political renewal in redemptive, Messianic terms. Yet, despite their extension of religious consciousness to include this new political reality, the religious Zionists refused to acknowledge the need to change practices based on *halakhah* which reflected very different historical conditions. How can one participate religiously in statehood, asks Leibowitz, without recognizing the incongruity of practising a *halakhah* wherein Jews are not fully responsible for maintaining the overarching socio-political reality of the state?

Leibowitz presents a Jewish categorical imperative for the religious community: act in such a way that you could wish all Jews to act in a similar fashion. Leibowitz thus rejected the granting of military exemptions to yeshivah students and religious girls. He similarly rejected all other concessions to the 'special interests' of observant Jews.

3 Israel and *halakhah*

Leibowitz is a *halakhic* existentialist who believes that the decision to participate in statehood cannot find legitimization in a framework that mirrors the historical conditions of exile. Unlike *halakhic* reform movements in the diaspora which, he believed, were usually motivated by a desire for social accommodation and convenience, Leibowitz was uncompromising in his demand for individual discipline and conformity to the standards of *halakhah*.

Modernity and the desire for social integration had no normative weight in his eyes. Leibowitz believed that the impulse for change that grew out of the new Jewish political reality was legitimate and urgent, since it was indigenous to Judaism and reflected the Jewish situation itself. Given the dependence of Judaism on the existence and the life of a Jewish society and people, it is contradictory and inauthentic for *halakhists* to ignore the need to revise Jewish law in the light of the expanded scope of Jewish social and political responsibilities. There is, then, a striking - but logically consistent - dichotomy in Leibowitz's attitude towards *halakhah*. He is conservative and authoritarian regarding the personal dimension of *halakhic* practice (for example, *kashrut* and the laws of sexual purity). But at the same time he is boldly innovative in his call for reform in areas related to public life in the State of Israel.

This dichotomy highlights the unique nature of Leibowitz's philosophic agenda in contrast to that of most other Jewish thinkers in the twentieth century. Franz Rosenzweig and Hermann Cohen, for example, sought ways of legitimizing Judaism in a Christian society. Rosenzweig claimed that Judaism bore witness to the eschatological moment in history; Hermann Cohen focused on the messianic impulse of universality. Mordecai Kaplan tried to free Judaism from the problematic notions of supernaturalism and divine election and thus to facilitate the integration of Judaism into modern pluralistic societies. Joseph Soloveitchik and Abraham Heschel aimed at renewing Judaism as a serious option for the individual in modern society. Soloveitchik tried to enliven the *halakhic* option by presenting Judaism as a compelling existential drama; Heschel wanted to rehabilitate the theological and spiritual sensibilities of the individual Jew. For Leibowitz, by contrast, the problem was not Christianity or the philosophical critiques of religion, but whether Judaism could be a viable and authentic possibility for an autonomous political community. While in the Diaspora, Judaism has to deal with the problems of the individual and individual relations with the surrounding culture. But in Israel the community has precedence over the individual. The individual now needs to be convinced that Judaism is an acceptable framework for the whole of society. The unique character of Leibowitz's existentialism is that it is directed towards providing for the authenticity of life as a member of the community.

Lenin, Vladimir Il'ich (1870-1924)

Lenin, leader of the October 1917 Revolution in Russia, wrote mainly about politics and economics, but as a Marxist of his generation he assumed that ideas about society needed to rest on sound philosophical premises. He was a militant atheist. He also regarded any other version of 'materialism' than his own as being a perversion of Marxism. Initially his works proposed an epistemology based on a crude analogy with photography. But in the First World War he revised his ideas after studying Hegel, and began to emphasize provisionality in the pursuit of scientific knowledge. Nevertheless he never disowned his earlier writings. And after his death his confused philosophical oeuvre retained axiomatic status in Marxism-Leninism.

1 Marxism and the defence of 'materialism'

Lenin had an influence on philosophical debate and education in his country and abroad entirely out of proportion with his expertise. Born in Simbirsk in the Russian Empire, he studied Marx's writings in his adolescence and became a follower of Georgii Plekhanov, who was the leading intellectual influence upon the clandestine Marxist groups in the Russian Empire in the 1880s and 1890s. Lenin's early articles took economic development and political struggle as their main themes. But he never lacked interest in questions of philosophy. On most fundamental questions he was Plekhanov's pupil, and proud of the fact. In so far as he intervened in the Russian Marxist discussions on epistemology, he contented himself with two activities: his repudiation of all religious belief and his castigation of the growing influence of Kant's ideas upon several prominent Russian Marxist thinkers.

He was equally opposed to the attempt by a group within his own section to inject a voluntarist element into Russian Marxist theory by linking it with the empiriocriticism of Mach (see Russian Empiriocriticism). Its main proponent, Aleksandr Bogdanov, was for some years an ally of Lenin in the Bolshevik faction which was formed after the Second Congress of the Russian Social-Democratic Labour Party in 1903. Bogdanov had always felt uneasy about central aspects of Plekhanov's philosophical work; and as Bogdanov and Lenin fell out about general political and cultural policy, so they were drawn into exposing their private dispute on epistemology. Lenin to a great extent stuck by Plekhanov's tenets. Above all, he followed Plekhanov in asserting that the 'external world' exists independently of human cognition. In treating the mind-matter dichotomy, he propounded that 'matter' imposed itself upon 'mind'. Indeed Lenin felt that Plekhanov described the process too weakly. Whereas Plekhanov imagined the mind as registering 'external reality' through a series of 'hieroglyphs', Lenin declared the process to be unmediated by any such process: instead the mind was supposedly a mechanism akin to a camera - and Lenin believed that cameras had the capacity for the exact registration of 'external reality'.

The extraordinary optimism of Lenin's epistemology is displayed in the conclusions he drew from this argument. In particular, he claimed that the Marxist mode of understanding society enabled its proponents to attain 'absolute truth'. To the counter-argument that such a claim would render obsolete any further research on economics, politics and culture, Lenin declared that *Das Kapital (Capital)* had yielded up only a portion of the available absolute truth. Nothing in Marx's *magnum opus* was going to be disproven; on the contrary, it would stand as a monument of unassailable verity. According to Lenin, *Capital* also laid down the necessary guidelines whereby to contribute further portions of absolute truth. Thus Marxism was 'scientific'; it was militantly 'materialistic', atheistic and began from the premise that the material and social world were in constant flux and that the study of changing phenomena was permanently required.

These opinions were stridently asserted in *Materializm i ėmpiriokrititsizm (Materialism and Empiriocriticism)*, the tract Lenin issued against Bogdanov in 1909. His style was overtly political. He affirmed that there were two 'parties' in philosophy: materialism (which he advocated) and idealism (which he opposed) (see Partiinost'). By entering into contention against Lenin, Bogdanov had removed himself from the only acceptable party - and Lenin the politician argued that by the same action Bogdanov had left the path of revolution and had abandoned organized Marxism. Lenin treated any refusal to espouse his own narrow version of Plekhanovite Marxism as a lurch into idealism that could eventually result in a resurgence of religious belief. As it happened, some among Bogdanov's political associates - notably Anatolii Lunacharskii and Maksim Gorkii - were contemporaneously developing a form of Marxism which proposed a kind of collective deification of the working class. This had

become known as 'god-building', and gave Lenin his polemical opportunity to write off all his opponents among Bolsheviks as aiming to effect a *rapprochement* with religion.

Bogdanov, who was a far subtler student of contemporary philosophy than his antagonist, did not take this lying down. He pointed out that Lenin's notion of absolute truth was antiscientific and metaphysical. Lenin made obeisance to Marx and Engels in a style of ritualist religion. Bogdanov argued that Marx had never made many of the claims made by Lenin in his name, and that the basic premise of any reasonable interpretation of Marxism should be that all analyses - including Marx's own - were merely provisional. Nor did Bogdanov fail to poke fun at Lenin's primitive understanding of how a camera works.

2 The exploration of 'dialectics'

Yet it would be wrong to give the impression that Lenin was merely exploiting philosophy for political advantage. At a basic personal level, his concern about epistemology was genuinely felt. Lenin made the assumption that any 'correct' (a favourite adjective!) statement about politics or economics had to be rooted in a 'correct' philosophical position. This, for him, was essential to Marxism. It consequently seemed to Lenin that if he disagreed with rival Marxists about their politics or economics, then a philosophical discrepancy must somehow lie at the foundations of the disagreement. Never was this clearer than in the First World War, when Lenin furiously objected to the policies pursued by the German Marxist theoretician Karl Kautsky. Kautsky had refused to make a clean break with the German Social Democratic Party over its decision to vote war credits to the German government. Lenin denounced this as a betrayal of socialist internationalism, and his reaction was not only to polemicize against Kautsky politically but also to investigate the philosophical premises implicit in Kautsky's wartime writings.

And so Lenin studied not only Marx and Engels but also those earlier philosophers who might help him understand the origins of Marxist epistemology. This brought him especially to Hegel and Aristotle; for his intuition was that Kautsky had an excessively deterministic approach to Marxism and underestimated the importance of 'dialectical' thought - of which both Hegel and Aristotle were notable exponents. Lenin was pretty thorough: he read Aristotle in a bilingual text which included the original Greek. He also re-read Marx's *Theses on Feuerbach*. Lenin's studies surprised and delighted him. With more than a touch of immodesty he decided that 'not one Marxist has completely understood Marx in the past half-century'.

His wartime notebooks on philosophy were meant to provide the material for a large, convincing exposition of the need for 'dialectics' to be bedded in the core of Marxism. His various jottings, which were not published at the time, exhibit several changes of stance from *Materialism and Empiriocriticism*. He abandoned his simplistic reflectional theory of cognition. Instead he stressed that human perception was a process of interaction not only between mind and matter but also between mind and concepts. Furthermore, he urged that the validity of theory could be judged only by 'practice' (*praktika*). In this fashion he was unwittingly moving close to the philosophical stance of his old adversary Bogdanov, who held that knowledge had to be obtained experimentally and could never be more than provisional in character. Lenin came to his new conclusions independently of Bogdanov. For whereas Bogdanov's ideas were a fusion of Marx and Mach, Lenin had refreshed his ideas by looking at Hegel - and continued to revile empiriocriticism as a reactionary doctrine.

Hegel's writings, especially those which dwelt on dialectical processes, by contrast had a strong attraction for Lenin, who contended that Hegelianism provided Marx and Engels with the key understanding that 'interruptions of gradualness', 'leaps' and 'breaks', were basic to the functioning of both the material and the social universe. Dialectics thereby became a philosophical justification for political revolution; and Lenin contended that it was precisely on this point that Kautsky had refrained from coming to terms with authentic Marxism. Lenin also argued that Kautsky had ignored the need for philosopher-revolutionaries to take chances, to speculate, to dream. Lenin had said something along these lines in his famous political treatise of 1902, *Chto delat' (What Is To Be Done?)*; but in the First World War such an argument became virtually a credo: 'The approach of mind (man) to a particular thing is…complex, divided, zigzaggish, *including within itself* the possibility of a flight of fantasy from life.…It is stupid to deny the role of fantasy even in the strictest science'.

Yet simultaneously Lenin, who was an intelligent but confused amateur in philosophy, retained much of the views expressed in *Materialism and Empiriocriticism* in 1909. As ever, he insisted that man's abstract conceptions about the world derived from 'a knowledge of the pattern of the objective links of the world'. His belief about there

being two entirely separate camps in philosophy, materialism and idealism, was unshaken. And he jotted down in his notebooks that there was no reason to deny the attainability of 'living, fruitful, true, powerful, omnipotent, objective, absolute human knowledge'. In 1920, furthermore, when he fell into public dispute again with Bogdanov (and indeed with fellow-Bolshevik Party leader Nikolai Bukharin), Lenin ordered the republication of *Materialism and Empiriocriticism*.

3 Lenin's philosophical legacy

Consequently Lenin left a legacy of great contradiction. He had changed much of his thought, but had done this by adding bits without excising earlier ones. As a philosopher he would hardly deserve a footnote in the history of twentieth-century thought if it had not been for his political career as the founder of the USSR. In everything he wrote he showed greater confidence than expertise. Even in most of his apparently original interpretations of Marx, he had largely been anticipated by Bogdanov. In his analysis of Hegel and Kant he misrepresented the differences between the two. Nevertheless in death he became the object of a secular state. Lenin himself had never claimed to be more than a follower of Marx. Nor had he attempted to assemble all his various political, economic and philosophical works into a single, authoritative set of tenets. This was done for him by his successors, especially Stalin; and his writings were codified and designated as Marxism-Leninism.

For most of the ensuing decades it was *Materialism and Empiriocriticism* which was used as the supreme philosophical text of the regime (although the *Philosophical Notebooks* became more widely discussed after Stalin's death in 1953). Even so, there was enough confusion and incompleteness in Lenin's published thought for Soviet philosophers to have plenty to argue about. The practice of philosophy in the USSR, cramped and abused as it was, would have had an even harsher environment if Lenin had been a more expert epistemologist.

Leont’ev, Konstantin Nikolaevich (1831-91)

One of the more original and provocative nineteenth-century Russian thinkers, Leont’ev directed a powerful intellectual attack at the dominant historical movement of his time: the process of modernization that was sweeping across Western Europe and making inroads into Russia. Leont’ev resisted the sociopolitical aspects of this process: the spread of democratic, egalitarian and constitutional principles. He also resisted its cultural and psychological aspects: the emergence of a standardized, homogenized mode of life and set of values.

Leont’ev defended the traditional values and institutions of monarchy, established Church, aristocracy and - especially - the distinctiveness and variety of national cultures. It was this distinctiveness, based on the isolation of nation states, that he saw as increasingly threatened by the advancing technologies of transport and communication.

1 Social philosophy and philosophy of culture

Konstantin Nikolaevich Leont’ev was born into a gentry family in the village of Kudinovo. He studied medicine at Moscow University and served as a military surgeon during the Crimean War, 1853-6. During his first two decades of literary activity (1854-76) he wrote mostly short stories and novels. His talent was recognized by Ivan Turgenev, who helped and encouraged him. Over the next two decades (roughly, 1872-91) Leont’ev produced a flood of brilliant and disturbing philosophical and political essays. He served for a decade as a Russian diplomat in various parts of the Ottoman Empire, 1863-73; he also worked in the Censor’s Office in Moscow, 1880-7. In 1871 he experienced a spiritual crisis and lived for a year in a Russian monastery on Mount Athos. His efforts to become a monk were gently, and wisely, rebuffed by his spiritual advisors, who felt that he was not yet ready to give up the ‘world’ of writing and publishing. He in fact took secret monastic vows a few months before his death, at the Trinity Monastery near Moscow.

Leont’ev has often been called a ‘Russian Nietzsche’, not in the sense of a Russian thinker influenced by Nietzsche, since he died before Nietzsche’s ideas became known in Russia (see Nietzsche: impact on Russian thought). Rather, it is sometimes claimed that Leont’ev anticipated Nietzsche’s main doctrines. This claim is seriously misleading. Leont’ev did share, in advance, Nietzsche’s stress on the priority of aesthetic over moral and practical values; his ‘aesthetic immoralism’ dates from the mid-1860s, a time when the dominant Russian Nihilists and Realists were deriding aesthetic values (see Russian Materialism: ‘the 1860s’; Nihilism, Russian). For example, a leading character in an early Leont’ev novel made the shocking assertion: ‘*A single century-old magnificent tree is worth more than twenty faceless men*; and I will not cut it down in order to be able to buy medicine [to treat] the peasants’ cholera!’ (1912-14, vol. 1: 306; emphases added).

Leont’ev also agreed with Nietzsche in celebrating the ‘poetry of war’, regarding security and comfort as deadening to cultural creativity; and of course he was entirely at one with Nietzsche in opposing the levelling and standardizing tendencies of the time. But there were a number of key differences. For Nietzsche, Christianity and democracy (and indeed socialism) were on the same side; in contrast Leont’ev spoke of the ‘Antichrist of democracy’. Leont’ev embraced strong nation states and state churches, both of which Nietzsche opposed. There is no counterpart in Nietzsche’s work to Leont’ev’s sweeping condemnation of modern technology. Leont’ev preached what he called the ‘poetry of *life*’ - the social and historical life of nations and ethnic groups in all its colourful diversity. Nietzsche preached the ‘poetry’ or ‘aesthetics’ of a universal *high culture*. Nietzsche accepted, and Leont’ev rejected, a powerful orientation towards the remote historical future. Leont’ev remained a Christian, preaching ‘love of one’s neighbour’; Nietzsche, the ‘anti-Christian’, preached ‘love of the far-off’, that is, ‘love of the high culture of the remote historical future’ and endorsed ‘instrumental cruelty’ towards one’s neighbours who are weak, sickly and uncreative. In a word, Leont’ev embraced, while Nietzsche repudiated, ‘good Samaritanism’. At the same time, Leont’ev introduced a highly original corrective, one which might well be considered ‘Nietzschean’: he insisted that Christian charity not be one-sidedly ‘democratic’. It should not be directed only at suffering workers or wounded soldiers (of whom Leont’ev had had direct experience during the Crimean War); it should include the powerful and privileged in their hour of need, for instance, defeated generals and aristocrats abused by the mob.

Leont’ev’s rejection of modernity is more sweeping than Nietzsche’s. In fact, the only aspect of the many-faceted

process of modernization that Leont’ev accepted was its stress on the subjectivity and - with qualifications - freedom of the individual person. On this point Leont’ev went further in Hegel’s direction than Nietzsche was prepared to do.

Leont’ev offers many impressive catalogues of the glories of sociopolitical and cultural diversity and vividness in ancient Greece and Rome and in medieval Europe, along with catalogues of the horrors of sociopolitical and cultural monotony and drabness in present-day Western Europe and - increasingly - Russia. The former he celebrated as ‘the poetry of life’; the latter he castigated as its ‘prose’ or ‘prosiness’. Here is one example, which sets out four kinds of differences that are being eliminated by the hated process of modernization: (1) social (the difference between a peasant, a nobleman and ‘a marquis in velvet and plumes’); (2) occupational (that between a soldier and a priest); (3) national-ethnic (that between a Basque and a man from Brittany, or between a Tyrolian and a Circassian); and (4) ‘intrareligious’ (that between ‘a Trappist in a hair shirt’ and a prelate in brocade). In this fourth difference Leont’ev would appear to have overshot his mark: even in the secularizing Europe of the late nineteenth century there was still a clear distinction between a Trappist in his hair shirt and a prelate in brocade.

The violence of Leont’ev’s repudiation of technology - both the principal forms already familiar in his own day (for instance railroad and telegraph) and those being introduced during his final years (telephone, electric light and so on) - is surprising. So is his claim that such ‘peaceful’ technology is much more destructive than the newer technologies of war (like the machine gun). But Leont’ev’s point is that these faster, more efficient, more pervasive forms of transport and communication are undermining the ‘isolation of states’ and national and ethnic cultural traditions, thus facilitating the general process of standardization and homogenization of culture. Like other aspects of the modernization process, technological advance is reducing the vivid poetry of life to colourless prose.

2 Philosophy of history

In 1869-71 Nikolai Danilevskii, in his influential book *Rossiia i Evropa (Russia and Europe)*, set out a large-scale theory of ‘cultural-historical types’ intended to show that the Slavic-Russian type possessed hitherto unrecognized cultural vitality and a special promise of future cultural creativity. Leont’ev’s philosophy of history was similar to, but in important ways distinct from, Danilevskii’s. Like the latter, he used an essentially biological model of historical development. Historical cultures, like living organisms, develop from a stage of ‘initial simplicity’ to a second stage of ‘flourishing complexity’ and then sink, through a third process of ‘levelling interfusion’, to organic decay and death. Western Europe, which had achieved its stage of flourishing complexity in the Renaissance, was already far advanced in the terminal process of ‘levelling interfusion’. Leont’ev estimated the life span of historical cultures at about 1,200 years and sometimes asserted - with the Slavophiles - that Russia was a younger culture than Western Europe and therefore had more of its period of flourishing complexity still ahead of it. But at other times, and more typically, he claimed that nineteenth-century Russia possessed a unique combination of institutional elements - autocracy, Russian Orthodoxy and a system of deep and stable class divisions - which would make it possible to ‘freeze Russia over’ and thus save it from the creeping Western European ‘rot’. Note that he claimed no special superiority - as Danilevskii had - for the uniquely Slavic elements of Russian culture; indeed, he stressed that all were derived from a non-Slavic source, namely Byzantium, that was *Greek* in language and culture.

Leont’ev sometimes spoke of his own position as ‘anti-European’, and one of his critics accused him of pervasive ‘miso-Europeanism’. Both terms are misleading. Leont’ev’s animus was directed against the process of modernization that was coming to Russia from Western Europe, not against Western Europe as such. As we have seen, he admired much in Western European history up to the Renaissance, specifically including the Roman Catholic Church and the institution of the Germanic Knights. At the same time the unifications of Italy and Germany that were under way in Leont’ev’s lifetime struck him as destructive of the diversity of ‘ethnic’ or ‘regional’ cultures of the various parts of the newly unified national wholes (say, Venice and Naples, or Bavaria and Prussia). It is true that Leont’ev was enchanted by the rich cultural diversity that he encountered during his stays in Greece, Turkey and the Balkans, and credited this to their more complete isolation (than Russia’s) from Western European influences. But Leont’ev’s fundamental protest was against modernization, not against Europe as such.

Looking sombrely into the future, he saw the triumph of a worldwide socialist movement - not because the

socialists were right but because their principal adversaries, the liberals, were wrong. Leont'ev even envisaged the possibility that such a socialist movement - 'the feudalism of the future', as he called it - might be headed by a Russian tsar!

3 Philosophy of religion

From the beginning Leont'ev's approach to religion, like his approach to secular matters, had a strong aesthetic colouring. He was charmed by the beauty of the Russian Orthodox service - the singing, the icons, the incense. But later his religious convictions took a severe 'Byzantine' turn and he came to stress the fear of God, ascetic discipline and a profound disillusionment with all things earthly as merely 'a passing dream'. In his final letters to Vasilii Rozanov Leont'ev commented bitterly that 'Christian preaching' was joining forces with the hated modernization process to 'kill the aesthetics of life on earth'. He added, in what appears to have been a tone of quiet desperation: 'We must help Christianity even at the cost of our beloved aesthetics' (letter of 27 May 1891).

Turning to the main proponents of a 'renewed' Christianity in Russia in his time, Leont'ev found both Tolstoi (he was right in this) and Dostoevskii (here he was wrong) guilty of falling into a humanistic 'rose-coloured' Christianity that verged on 'anthropolatry' - 'a new faith in *earthly man* and in earthly mankind - in the ideal *self-sufficient, autonomous* worth and dignity of the *individual person*' (1912-14, vol. 8: 160; original emphases). He was especially infuriated by Tolstoi's presumption in editing and rewriting the New Testament and by Tolstoi's reference, in a conversation with Leont'ev, to '*my* Gospel'.

The originality and depth of Leont'ev's ideas about history, society, politics, culture and religion led to his being 'heard but not heeded, read but not understood' in his own time and for many years after his death. It is only in the twentieth century, especially during its final decade (and mostly in post-communist Russia) that Leont'ev's provocative and unsettling works have been widely reprinted and seriously discussed.

Leśniewski, Stanisław (1886-1939)

Leśniewski was one of the most distinguished members of the Warsaw School of Logic. His scientific development can be divided into two periods. In the first 'philosophical' period (1911-16), he worked on problems on the borderline of logic and philosophy. In the second period (1916-39), Leśniewski concentrated on mathematical logic. Together with Łukasiewicz, he established the Warsaw School of Logic. Leśniewski intended to build a comprehensive system of logic which might be the basis for all knowledge. His system, unorthodox in many points, consists of three parts: protothetic (a generalized sentential calculus), ontology (a calculus of names) and mereology (a theory of the whole/part relation).

1 Life

Leśniewski was born on 30 March 1886 in Serpukhova, Russia. He studied philosophy in Leipzig and Munich (where he attended courses by Cornelius, Geiger and Pfänder). In 1910 he went to Lwów to prepare his Ph.D. thesis on existential sentences under the supervision of Twardowski; he obtained his Ph.D. in 1919. In 1915-18 he lived in Moscow, where he taught mathematics in Polish schools. At that time, he was a 'leftist' in his political views and delivered several lectures on Marxist philosophy; he entirely abandoned this ideology after the October Revolution. In 1919 Leśniewski became the professor of philosophy of mathematics at the University of Warsaw. He died of cancer on 13 May 1939.

2 Early views

In his Ph.D. dissertation, Leśniewski argued that all negative existential sentences (for example, sentences of the type '*x* does not exist') are self-contradictory. This was a direct consequence of the thesis that every sentence refers to an object. Leśniewski's doctoral dissertation was written from the point of view of a very traditional grammar and logic; he was at that time very strongly influenced by Cornelius, J.S. Mill, Marty and Husserl.

Leśniewski's first contact with new ideas in logic took place in 1911, when he read *On the Principle of Contradiction in Aristotle* by Łukasiewicz (PAU, Kraków, 1910). Leśniewski reported his contact with this book in the following way:

> In the year 1911…I came across a book by Jan Łukasiewicz about the principle of contradiction in Aristotle.…This book became a revelation…for the first time in my life I learned of the existence of the 'symbolic logic' of Bertrand Russell as well as his 'antinomy' regarding the 'class of all classes, which are not elements of themselves'.
>
> (Leśniewski 1992: 181)

Leśniewski undertook to resolve Russell's antinomy (see Russell, B.A.W. §§4-8). After some unsuccessful attempts within standard set theory, he came to the view that the concept of a class must be reinterpreted in terms of the mereological concept of an aggregate. Given this interpretation, the expression of 'the class of all classes which are not elements of themselves' has no reference and the antinomy disappears. Leśniewski's analysis of the concept of class was the starting-point for his mereology.

Leśniewski's other investigations in the first period concerned the principle of contradiction, the principle of the excluded middle, and the concept of truth. He tried to prove the principle of contradiction via a proof of the sentence 'no object contains contradictions'. But in the case of the principle of the excluded middle, Leśniewski denied its universal validity, because he maintained that sentences of the type '*a* is *b*' with empty names in the place of '*a*' are false; thus, both '*a* is *b*' and '*a* is not *b*' are false. Leśniewski also defended the absolutism of truth: every truth is eternal and sempiternal.

Leśniewski's own evaluation of his early works was decisively negative:

> I struggled with a number of problems which were beyond my powers at that time.…I have mentioned those works desiring to point out that I regret that they have appeared in print, and formally 'repudiate' them herewith…affirming the bankruptcy of the 'philosophical'-grammatical work of the initial period of my work.
>
> (Leśniewski 1992: 197-8)

However, a closer analysis shows clearly that Leśniewski did not reject all of his views from the early writings. As well as the mereological conception of class, he retained the absolutist conception of truth and the view that all sentences of the type '*a* is *b*' are false if '*a*' is an empty name.

3 General remarks on Leśniewski's logical systems

Leśniewski's system of logic comprises three systems: protothetic (an extended sentential calculus), ontology (a calculus of names) and mereology (a theory of mereological classes). This succession indicates the logical order of those systems. However, Leśniewski invented his systems in just the opposite succession. Mereology appeared as the first in 1916. Then, at the beginning of the 1920s, he completed his ontology and protothetic.

There is a considerable difference in style between Leśniewski's early work and his later work on protothetic and ontology (see Leśniewski 1929 for example). A booklet of 1916 on the foundations of the general theory of classes is written in an informal manner. Then, Leśniewski, under Chwistek's influence, began to employ formal languages as tools in doing logic. His formalism was very extreme in the sense that he required a complete codification of the languages of formal systems. Hence, he regarded Russell and Whitehead's *Principia Mathematica* as a very obscure work, full of linguistic confusions: for example, it conflates object-language and metalanguage. Indeed, Leśniewski was probably the first person to point out that Frege achieved much more precision than Russell did. On the other hand, Leśniewski rejected formalism understood as a view that logic and mathematics are games with symbols devoid of meaning. He called his view 'intuitionistic formalism', although this view has nothing to do with Intuitionism as a position in the foundations of mathematics.

Leśniewski was a radical nominalist. He took formal systems to consist of concrete expressions (symbol-tokens, to use a popular label). Thus, on his view, formal deductive systems are always finite in the number of formulas, although they are 'unfinished' or 'unbounded', because it is always possible to add further formulas. Hence, his systems are equipped with very precise directives for introducing new expressions into the body of a system. A special role is played by the rules of definition for new signs. Leśniewski was the first logician who explicitly stated the principles of correct definition in formal systems. His systems are axiomatic, but he also used techniques of natural deduction. Certainly, his logic is peculiar, if by a deductive system we understand what is typically meant. However, it is commonly recognized that his formalization is the most precise in the entire history of logic (see Nominalism).

4 Protothetic

Protothetic is a generalized sentential calculus. It is a sentential logic with quantifiers which bind variables of several semantic categories: sentential variables, functorial variables which range over functors forming sentences from sentential arguments, functorial variables which range over functors of functors, and so on. In general terms, quantifiers in the theorems of protothetic bind variables of an arbitrary semantic category which are definable when we start with a category of sentences.

The full system of protothetic is based on equivalence as the sole primitive term. An important result for the formalization of protothetic on the basis of equivalence was obtained by Tarski (in 1923) who showed that equivalence and the universal quantifier suffice to define negation and conjunction. The functions of protothetic are not limited to giving rules for sentential connectives, because this system also contains rules for the quantifiers which are used in ontology and mereology. Protothetic is, in a sense, an absolute sentential logic, because the principle of bivalence and the principle of extensionality are among its theorems. Thus, protothetic can be considered as an adequate representation of the classical idea of logic. Protothetic is consistent, but the problem of its completeness is not yet fully solved. What is known is that elementary protothetic (that is, protothetic with quantifiers restricted only to sentential variables) is complete.

5 Ontology

Ontology is the system which arises when the functor 'is' is added to protothetic. This functor forms sentences from names. Ontology considers the grammatical structure '*a* is *b*'. Such a sentence is false if its subject is empty or refers to more than one object. This meaning is captured by the axiom of ontology which says: for any *a* and *b*, the sentence '*a* is *b*' is equivalent to the conjunction of sentences (i) for some *c*, *c* is *b*, (ii) for any *c* and *d*, if *c* is *a* and *d* is *a*, then *c* is *d*, (iii) for every *c*, if *c* is *a*, then *c* is *b*. The intuitive content of the axiom is this: '*a* is *b*' is true

if and only if '*a*' is non-empty, there is only one object to which '*a*' refers ('*a*' is a singular name), and whatever falls under '*a*' also falls under '*b*'.

Ontology is supplemented by several definitions of sentence-forming functors operating on names. Two examples illustrate this matter: (i) for any *a*, *a* exists if and only if for some *x*, *x* is *a*; (ii) for any *a*, *a* is an object if and only if for some *x*, *a* is. (i) gives a definition of existence, and (ii) of being an object. These examples show how 'is' is understood in Leśniewski's ontology. This meaning of 'is' closely corresponds to the sense of *est* in Latin as the copula in 'Socrates est homo'. 'Is' in the considered meaning has no spatiotemporal connotations and it does not indicate the membership-relation from set theory. Also, Leśniewski's 'is' is different from 'is' in 'there is justice' or 'every man is mortal'. In general, one must be very careful in translating the basic functor of ontology (symbolically denoted by 'Čepsiv;') by the English 'is', because the latter is modified by articles which do not occur in Latin (or Polish).

Leśniewski's ontology is consistent, but the question of its completeness is still open. Ontology performs the role of predicate logic, but there are also important differences. For example, identity is definable in first-order ontology, whereas it is not definable in the standard first-order logic, and the theorems of ontology are true in any domain, including the empty one. Why was this system called 'ontology'? Leśniewski chose this term because he conceived ontology as a logical theory which offers a general theory of objects in the sense of Aristotle and his followers.

6 Mereology

Mereology is a theory of classes, but classes in their mereological (collective) sense, contrary to the standard set theory which considers classes in their distributive meaning. The crucial differences between these conceptions of class is that elementhood in mereology is transitive, but membership in set theory is not: if *x* is a mereological element of *y* and *y* is a mereological element of *z*, then *x* is also a mereological element of *z*, but the comparable rule does not hold for membership. Another peculiarity of mereology is that there is no empty set.

For Leśniewski, the mereological concept of class is more intuitive than the concept of set in the distributive sense. He argued that intuitions concerning collective classes are perfectly consistent with Cantor's famous statement that any manifold which can be considered as a unity is a set (see Cantor, G.; Cantor's theorem). Naturally, a problem arises whether mereology is as strong as set theory. The answer is negative: mereology is weaker (see Mereology).

7 Concluding remarks

Leśniewski influenced the development of logic in Poland very strongly. Together with Łukasiewicz, he trained many logicians, including Tarski (who obtained his Ph.D. under Leśniewski), Lindenbaum, Wajsberg, Sobocinski, Słupecki and Lejewski. Sobocinski and Lejewski became his main followers. In spite of his unorthodoxy in logic, Leśniewski invented several ideas which belong to the standard logical canon. For example, he initiated the theory of syntactic categories developed by Ajdukiewicz in the 1930s. Leśniewski revived Frege's object-language/metalanguage distinction and used it to suggest a solution to the Liar paradox (this solution was later developed byTarski); he also stated the conditions for correct formal systems commonly accepted by Polish logicians.

His own logical ideas are on the margin of the mainstream of logic. However, an interest in Leśniewski's logical systems is an important ingredient of logical investigations, and studies on his logical systems have been undertaken in all parts of the world, particularly in Poland, in England (among Lejewski's students - the Manchester School), and in the USA (among Sobocinski's students - the Notre Dame School). These studies have concentrated on the properties of Leśniewski's systems, and their relations to standard theories, like first-order logic, Boolean algebra and set theory. There are also attempts to apply his ideas to the analysis of natural language; for example, ontology has been interpreted as a theory of plural terms. Leśniewski's logical ideas also influenced philosophy. His ontology is nominalistic, because it admits only particulars as values of variables, and this idea was an important influence on Kotarbiński. Thus, it can be said that there is a distinctive Leśniewskian paradigm in logic.

Lessing, Gotthold Ephraim (1729-81)

Gotthold Ephraim Lessing occupies a central place in eighteenth-century European belles-lettres. He was a significant religious and theological thinker whose work puzzled his contemporaries and still provokes debate. He has been variously called a deist, a concealed theist, a Spinozist-pantheist, a panentheist, and an atheist. He was a significant dramatist whose major works include Minna von Barnhelm, known as the first modern German comedy, and Nathan the Wise, which places Lessing in the tradition of eighteenth-century toleration and humanism. He was an active promoter of the contemporary German theatre and an influential drama critic and theorist. He had broad classical and antiquarian interests. And he has some claims to being one of the early developers, if not a founding father, of the discipline of philosophical aesthetics.

Philosophically, Lessing belongs to the tradition of G.W. von Leibniz and Christian Wolff and was familiar with the post-Wolffian aesthetics being developed by Alexander Baumgarten and his follower Georg Friedrich Meier. Most importantly, perhaps, Lessing was acquainted with Moses Mendelssohn, to whose work his own philosophical writings bear many similarities and who read and commented on Lessing's aesthetic writings. But Lessing cannot be identified with any of these philosophical sources and influences. His work retains many rationalist presuppositions, but Lessing also consciously sought a more inductive approach. He adhered to neoclassical standards with respect to beauty and the application of rules of art, but severely qualified those standards by justifying them empirically and appealing to emotional effects rather than to ideal forms or Cartesian clarity. Lessing's aesthetics must be inferred from his work, particularly from his Laocoon, some of the numbers of the Hamburg Dramaturgy, and to a lesser extent from short works such as 'How the Ancients Represented Death' and the letter of 26 May 1769 to Friedrich Nikolai. What emerges is a sometimes inconsistent and fragmentary aesthetic, which one might describe as a critical rationalism.

1 The interpretation of the 'Laocoon' group

Lessing's *Laocoon* is a complex work that embeds an even more complex aesthetic. The published text, which was projected as the first part of a longer work that Lessing never completed, interweaves two principal themes. The first is a dispute with Johann Joachim Winckelmann over the interpretation of the statue group *Laocoon*. Winckelmann had claimed that the expression on the face of the priest Laocoon when he is fatally entangled with the serpents is more restrained than the scream described by Virgil in the *Aeneid* when dealing with the same incident. Winckelmann attributed this restraint to the classical Greek virtues of control and dignity in adversity, and ultimately to a superior Greek sense of ideal form. Lessing had seen only engravings of the *Laocoon* and not the statue itself, even as a copy, and he therefore conceded to Winckelmann the interpretation of the group itself. (This would not be granted by many contemporary art historians who find the *Laocoon* extremely emotionally wrought compared to classical models.) But Lessing disputed the significance of Winckelmann's interpretation by pointing out that classical painting and sculpture were frequently described as depicting extreme suffering; thus it was not Greek virtue as such that restrained the artists in this case. Rather, Lessing argued, artists are constrained by their medium. The restraint shown by the Laocoon sculptors is a product of their awareness of the rules of visual media. Virgil, as a poet, is bound by different rules.

2 The comparison of painting and poetry

Comparisons between painting and poetry were a staple of eighteenth-century critical theory, and Lessing entered these debates with vigour. Fundamentally, he distinguished between the spatial properties of painting and the temporal properties of poetry. Painting and sculpture are grasped at once by visual perception. But poetry is understood sequentially. Lessing based rules about the appropriate means of imitation for each art form on this comparison. Painters and sculptors are limited to a single moment that they can capture completely. This, in turn, dictates the specific rules that give painting and sculpture access to beauty. If the *Laocoon* sculptors had tried to follow Virgil by depicting the distorted face of a screaming Laocoon, the viewer would have been overwhelmed with disgust by the immediate effect, and they would have failed in their attempt to show what was happening because sculpture could not hope to capture the scene's movement and action. It is limited to a 'pregnant moment', and in order to capture that moment, the sculptors had to abstract from the visual scene those parts of it that would convey the ideal beauty and restraint that was their true object. Virgil, on the other hand, could show change and

development. Poetry imitates action, not objects. The sequence of words corresponds to a sequence of events. Thus the scream and suffering are immediately qualified by what goes before and comes after. Instead of evoking disgust, the emotions are changed and qualified. In each case, Lessing insisted, it is the aesthetic whole that must be considered.

In spite of Lessing's emphasis on the difference between poetry as an imitation of action and painting as a spatial presentation, and his insistence that each has a different set of rules which cannot be reduced to a common set, he did not completely separate the art forms. They have a common object, beauty, and a common effect, pleasure. Lessing's argument is that neither can attain this common objective without restricting itself to its own rules. In principle, he granted relative equality to the different art forms. In practice, however, poetry is clearly the superior form. Painting and sculpture are limited in two ways. The doctrine of the pregnant moment limits painting and sculpture not just to certain techniques but also to certain 'objects'. Painting has a limited number of subjects available to it. And, while painting and sculpture gain a certain immediacy from their presentational forms, that very immediacy restricts them to a concrete, visual presence that makes it difficult for them to escape the present moment. When painting becomes allegorical in order to try to enhance its significance, it violates its own spatial rules. Poetry, on the other hand, is not subject to such limitations. It appeals to the imagination, not actual vision. It can depict emotions as well as objects. And it can use its extensive, moving forms to go beyond the mundane to the significance of beauty itself. The temporal forms of poetry enhance its effects while the spatial forms of painting act as limits.

3 Natural and artificial signs

In distinguishing painting and poetry, Lessing makes use of a more fundamental distinction between natural and artificial signs. This distinction was set out clearly by Mendelssohn, who distinguished natural signs from arbitrary signs. He described natural signs as those that are connected to their objects by properties of the object. Arbitrary signs have no such natural connection and are linked to their objects only by convention (1771: 1, 437). For example, a blush is a natural sign of heightened emotion, and a picture is a natural sign of its object by virtue of its resemblance. But the choice of sounds and letters in language, while it may have natural origins, is essentially arbitrary. Thus painting uses natural signs, while poetry, which depends on language, uses arbitrary signs. Lessing's dramatic theory explores ways in which arbitrary signs for the imitation of action can be converted to natural signs when they form dramatic wholes. The theory is essentially rationalist; its goal is to account for how the intuition available in art and nature can be adequate to concepts and ideas. But Lessing, by focusing on the effects, turned the theory in the direction of the critical object.

4 Lessing and rationalist aesthetics

Lessing's aesthetics is best understood in the context of the rationalist aesthetic that was being developed at that time in Germany, particularly by Alexander Baumgarten and Georg Friedrich Meier, under the influence of Christian Wolff. Lessing himself implicitly located his own position in the preface to *Laocoon*. The amateur is in the position of the audience while the philosopher formulates general rules, and the critic applies them - sometimes correctly, sometimes erroneously. Lessing occupied that critical position, and he took from the philosophers - Spinoza, Leibniz, Wolff, Baumgarten, Mendelssohn and others - general aesthetic rules. But in applying those rules, he modified them to an extent of which he himself may not have been aware.

In many respects, Lessing presumes an aesthetic that can be derived more or less explicitly from Leibniz. Its object is beauty, which is understood as the perfection of a whole. Ideal beauty is found in distinct ideas whose clarity comes from their uniformity. Their reflection is found in the corporeal beauty which is a harmony of parts. Moses Mendelssohn defined beauty as the intuitive cognition of perfection. A cognition is intuitive, he wrote, when its object is immediately present to our senses or when we attend to the object rather than the sign for the object (1757: 1, 170). Lessing's formulation was similar except that Lessing was more concerned with concrete, critical applications to poetry and painting. This led him to distinguish the different possibilities provided by the differences in media. Painting is adapted to material beauty (1766: 104). Poetry, on the other hand, is adapted to a different kind of description: that of the presentation of emotions (1766: 111). Ultimately, painting and poetry have the same object: beauty. Poetry, however, has the advantage of presenting effects and thus of giving an apprehension of beauty itself, while painting can only show material beauty in its outward forms.

All rationalist aesthetics implicitly denigrates both art and nature. Beauty is grasped intuitively, but there are two forms of intuition: the sensory and the rational. Rational intuition is capable of apprehending ideas distinctly without the confusion of images and parts. Thus, it is superior to the confused sensory intuition of perception and the imagination. No rationalist aesthetic completely escapes this limitation on the products of art and nature. However, Alexander Baumgarten argued that sensate intuition was the superior form if one considered its effectiveness in guiding people to beauty, and Lessing followed Baumgarten in this respect. But Baumgarten considered sensate intuition essentially quantitative. He reasoned that since description adds to the completion of an idea, the more descriptive a painting or poetic passage, the more aesthetically perfect it is, and hence the more 'poetic' and beautiful. Lessing explicitly rejected this quantitative argument in favour of a distinction based on the effects that can be achieved. Poetry, on Lessing's view, should not strive for extended descriptions; Homer limits himself to a single trait (1766: 79). Poetry's ability to focus selectively and thus enhance its effects gives it the advantage over painting.

Thus, while Lessing remains clearly within the rationalist circle if one compares him to such sentimentalists and sense-theorists as Lord Shaftesbury or Francis Hutcheson, he departs in significant ways from the syllogistic and axiomatic descriptiveness of more orthodox rationalist formulations. Art is basically imitation, but for Lessing, imitation is directed towards action and emotion as well as objects. Lessing was thus led to consider both rules and means in a more concrete, inductive way than the axiomatic, deductive procedures of rationalist metaphysics had dictated. Rules are justified not by their logical form but by their effects. Since it is pleasure which is aimed at, one must be prepared to adjust the rules to the observed results. At this point, Lessing is very pragmatic. Empiricist aesthetics in England and France developed along psychological lines; it attempted to predict how certain emotional effects followed from artistic practice and natural beauty. Rationalist aesthetics, on the other hand, began with principles of unity and harmony and attempted to derive their application as a set of rules for the production of art and aesthetic effects. Lessing trusts neither. Emotions are not really subject to rules (1766: 28). On the contrary, rules are judged by their effects. At the same time, Lessing acknowledges the superiority of science to art. The object of science is knowledge; it is not subject to control by anything other than truth. But the object of art is pleasure. Since pleasure is not absolute, it may be judged by other standards and subjected to control (1766: 14).

5 Lessing's critical practice and aesthetic principles

In a number of ways, then, Lessing, as a critic who employs the philosophical 'rules' of his rationalist contemporaries, complicated and modified those rules and practices in ways that enhanced their critical application. In the process, he sometimes exhibited contradictory impulses. His definition of art included both his aesthetic tendencies. In the course of discussing ancient artefacts, Lessing wrote: 'I should prefer that only those be called works of art in which the artist had occasion to show himself as such and in which beauty was his first and ultimate aim' (1766: 55). The goal of art is beauty, and beauty can be understood in terms of harmony and perfection. But the other specific difference cited is that the artist had occasion to show himself, and that expressionist aesthetic is potentially at odds with the imitation implied in the reference to beauty. Lessing did not believe that imitation is pleasurable in itself. But he did hold that it produces pleasure as a result of the mental activity it stimulates. If feelings and emotions are the proper objects of imitation, Lessing was looking in a place far removed from his rationalist sources. Given his own distinction between critic and philosopher, Lessing is a critical rationalist for whom the role of the critic is central.

His aesthetic remains critically grounded, but it also universalizes:

> The purpose of art is to save us this abstraction in the realms of the beautiful, and to render the fixing of our attention easy to us. All in nature that we might wish to abstract in our thoughts from an object or a combination of various objects, be it in time or in place, art really abstracts for us, and accords us this object or this combination of various objects as purely and tersely as the sensations they are to provoke allow.
>
> (1767-8: 226)

Art is neither pure sensate representation nor absolute truth. The former is too chaotic, too confused. The latter is beyond our finite limits. Lessing's use of the theory of natural and arbitrary signs, his combination of imitation and expression, of rules and genius, of feeling and absolute form may not always be consistent, but it has as its object a

middle ground which produces a critical aesthetic of considerable practical power.

Leucippus (5th century BC)

The early Greek philosopher Leucippus was the founder of atomism. Virtually nothing is known of his life, and his very existence was disputed in antiquity, but his role as the originator of atomism is firmly attested by Aristotle and Theophrastus, although the evidence does not allow any distinction between his doctrines and those of his more celebrated successor Democritus. He wrote a comprehensive account of the universe, the Great World-System*. The single surviving quotation from his work asserts universal determinism.*

Leucippus was a shadowy figure even in antiquity. Virtually nothing is known of his life. His birthplace was disputed; some sources associated him with one or other of the two principal centres of early Greek philosophy, Elea and Miletus, others with Abdera, the birthplace of Democritus. The statement in a number of sources that he was a pupil of Zeno of Elea may be merely an inference from the Eleatic influence on the foundations of atomism (see Democritus §2). Of his dates, all that can be said is that he lived during the fifth century BC: he was almost certainly older than Democritus, who is described by Aristotle and Simplicius as his 'associate' (*hetairos*), implying that Democritus was his pupil (as is also attested by Diogenes Laertius). In the post-Aristotelian period he was overshadowed by Democritus to such an extent that atomism came generally to be regarded as the work of the latter, while Epicurus and his successor Hermarchus are reported to have denied that Leucippus ever existed. His historicity is, however, firmly attested by Aristotle, who is the primary source for atomism. No list of Leucippus' works exists. The catalogue of works of Democritus produced by Thrasyllus in the first century AD contains two books entitled *World-System* (*diakosmos*), respectively, the *Great World-System* and the *Small World-System*, with a note that the school of Theophrastus attributed the former to Leucippus. It is probable that that attribution is correct, the attribution to Democritus being due to the overshadowing process mentioned above. The single quotation surviving from Leucippus is said by its source, Stobaeus, to come from a work *On Mind*; it is uncertain whether that title refers to a section of the *Great World-System* or to a separate work. The pseudo-Aristotelian treatise *On Melissus, Xenophanes and Gorgias* refers to 'the so-called arguments of Leucippus', presumably a reference to a work purporting to be by Leucippus.

Aristotle, followed by Simplicius, sometimes attributes the fundamentals of atomism to Leucippus (see, for example, Aristotle, *On Generation and Corruption* 325a23, b7). Elsewhere, however, and sometimes even in the same context (for example, *On Generation and Corruption* 325a1-2) Aristotle refers to Leucippus and Democritus jointly, and not infrequently to Democritus alone (as was the standard practice of later writers). That Leucippus was in some sense the pioneer is undoubted, but it is impossible to determine what elements of the theory of atomism are to be attributed to either, or to what extent their enterprise was collaborative. (For discussion of the principles of atomism, see Democritus (§2).) Of the two most detailed reports of the atomists' account of the formation of worlds, one is attributed by Diogenes Laertius to Leucippus (IX 30-3), and is presumably a summary of the account in the *Great World-System*. It ascribes the formation of worlds to agglomerations of atoms which, formed by chance collisions, develop a rotation in which atoms of different sizes are sifted out, the smaller being extruded into the infinity of space, the larger forming a spherical structure which gradually differentiates itself into a cosmos as the larger atoms sink to the centre and the smaller are forced to the outside. The rotation of the cosmic aggregates was apparently unexplained, and was according to some sources attributed to chance. This raises the question whether Leucippus believed that some events, such as the cosmic rotation, are objectively random, or are merely ascribed to chance in the weaker sense that their cause is undiscoverable. The single quotation, 'Nothing happens in vain, but everything from reason and of necessity' (fr. 2, Stobaeus, I 4.4), suggests the latter. While it could in isolation be understood as asserting universal purposiveness in nature, the secondary sources, including Aristotle, are unanimous that the atomists denied all purposiveness in natural events. Hence the quotation is best understood as asserting universal determinism; 'in vain' is understood as 'for no reason', and 'of necessity' specifies the reason for which everything happens - namely, the irresistible force of causation. On that interpretation, the cosmic rotation must have had some determinate cause, but a cause undiscoverable to us.

Levinas, Emmanuel (1906-95)

In the 1930s Levinas helped to introduce the phenomenological philosophy of Husserl and Heidegger to the French. Subsequently his work attained classic status in its own right for his attempt to explore the meaning of ethics from a phenomenological starting-point. In Totalité et infini (1961) (Totality and Infinity, 1969) Levinas locates the basis of ethics in the face-to-face relation where the Other puts me in question. My obligations to the Other are not contracted by me. They not only precede any debts I incur, but also go beyond anything I could possibly satisfy. In later works, most notably Autrement qu'être (1974) (Otherwise than Being, 1981) Levinas explores further the preconditions of this account, most especially by investigating the I that was said to be put in question in the encounter with the Other. In analyses that stretch phenomenology to its limits and beyond, Levinas finds alterity within the self.

1 Life and philosophical development

Emmanuel Levinas was born in Lithuania. In 1923 he went to Strasbourg University where his studies included the philosophy of Henri Bergson. From 1928 to 1929 Levinas was at Freiburg University, where he studied first with Husserl and then with Heidegger. This led him in 1930 to publish *La Théorie de l'intuition dans la phénoménologie de Husserl* (*The Theory of Intuition in Husserl's Phenomenology*, 1973) a reading of Husserl that was informed by Heidegger's criticisms of Husserl's intellectualism. Since that time almost all of Levinas' philosophical works have taken their point of departure from either Husserl or Heidegger. If the practice of a philosopher like Levinas can be summarized in a phrase, one would have to say that he works at the limits of phenomenology by investigating the enigma behind the phenomenon. Whereas what lies hidden is, for Heidegger, primarily the being of beings, for Levinas, it is the excess of being, or in Plato's phrase, the good beyond being.

Levinas first presented his own thought in his essay on 'Evasion' (1935) and two short studies published immediately after the Second World War, *De l'existence à l'existant* (1947a) (*Existence and Existents*, 1978) and 'Le temps et l'autre' (1947b) (*Time and the Other*, 1987). These works offer analyses of nausea, fatigue and insomnia, as well as of the alterity found in death, fecundity and eros. They were already part of an attempt to go beyond the thought of being, although it was not until 'L'ontologie, est-elle fondamentale?' (1951) ('Is Ontology Fundamental?'), which was largely a criticism of Heidegger, that it became apparent that Levinas intended to issue his challenge to the dominance of ontology within Western philosophy specifically in the name of ethics and the alterity of the other human being. During the war, Levinas had been imprisoned in Germany in a camp for French soldiers, but on his release and in response to the Nazi persecution of the Jews, which none of the members of his family left in eastern Europe survived, he renewed his involvement with the Judaism of his childhood. From that time his studies developed along two trajectories. His main philosophical works, *Totalité et infini* (1961) (*Totality and Infinity*, 1969) and *Autrement qu'être* (1974) (*Otherwise than Being or Beyond Essence*, 1981), which increasingly stretch the language of Western philosophy to its limits, were accompanied by confessional writings, such as *Nine Talmudic Readings* (1990) and *À l'heure des nations* (1994) (*In the Time of the Nations*, 1988) which translate Hebraic wisdom into the language of Greece, by which he meant the universal language of the West. Although Levinas insisted, especially at first, that the two kinds of writing were entirely distinct and appealed to different kinds of evidence, their separation is far from straightforward. Terms like 'election', 'persecution' and 'hostage' that Levinas explored in his writings on the Talmud have found their way into his philosophical studies. Although Levinas has refused to describe himself as a Jewish philosopher, the unity of his thought lies in his attempt to address the nonsectarian question of ethics after the Holocaust by employing the resources of both phenomenology and Judaism. In this entry I focus on his contribution to ethics as the portion of his work that has attracted most attention.

2 *Totality and Infinity*

The guiding insight of *Totality and Infinity* is that the Other human being in their separation calls me into question. In the face-to-face relation my self-assurance disappears and I find myself in bad conscience. Levinas does not look to ethics to restore good conscience. On the contrary, I never have the luxury of knowing that I did the right thing in any given situation. Nor is it simply a question of knowledge. I can never do enough. My obligations to the Other are unlimited, as well as being asymmetrical in the sense that I have no right to ask of the Other what the

Other asks of me. In society, furthermore, every effort to meet my obligations to one person comes at the expense of my efforts on behalf of the others. Levinas refuses all the standard ways of diminishing the impact of these impossible demands, such as conceiving ethics in terms of intention or employing the model of legal responsibility where I am only answerable for what is in my power. Levinas has readily conceded that he does not provide an ethics but only an account of the condition of ethics. It should be added that what he describes as ethics is very different from what has hitherto gone under that name among philosophers.

The reciprocal system of obligations that usually passes for ethics most often goes under the name of justice in Levinas' thought. Levinas finds the system of justice to be in accord with reason, but he finds that, just as the I is put in question by the Other within the face-to-face relation, so justice is put in question by the face of the Other. The ethical relation with the Other exceeds the third-party perspective of neutral reason. As a result, Levinas is quite explicit that his account of the ethical is not constrained by what he calls 'formal logic'. Since Derrida's 1964 essay on Levinas, 'Violence et métaphysique' (1967) ('Violence and Metaphysics', 1978) questions have been raised about whether such an account is possible, thinkable and sayable. These enquiries, far from being uniformly negative, have led to some of the most far-reaching developments within continental philosophy, not least in the works of Derrida.

The way in which ethics questions justice also serves as an answer to the frequently heard criticism that Levinas' thought has little to offer to political theory. It is true that he has not said much about society, but his challenge to the good conscience of ethics applies equally well to politics. Levinas refers in one place to the tears invisible to the bureaucrat. In this very simple way he draws attention to what grand schemes overlook. Nor is the relation between ethics and justice one-sided in favour of the former. Just as ethics in Levinas' sense keeps justice from being satisfied with itself, so justice can also serve as a corrective to ethics. If there was only one other person in the world, I could devote myself to that person, but because I live in society, I can address my obligations to the Other only by neglecting the others. It is here that the place of reason and calculation becomes important also for ethics. Levinas found a formula that encapsulated the interruption of ethics by justice when he described how the third party, in the sense of the whole of humanity, looks at me in the eyes of the Other.

3 *Otherwise than Being*

In *Otherwise than Being* Levinas returned to the way that the Other questions the identity of the I. To be for the Other is to be without identity. This led Levinas to introduce a new structure that he calls 'substitution' and which he summarizes with Rimbaud's formula 'the I is an other'. Levinas also says that 'subjectivity is being hostage'. He means by this that subjectivity is not the isolated ego of modern philosophy, but the restlessness of being disturbed by the other. For Levinas, questions which would seem to many to be the most fundamental of ethical questions, such as 'Why does the other concern me?', 'Am I my brother's keeper?' or, with reference to Shakespeare's *Hamlet*, 'What's Hecuba to me?', have already come too late for ethics. These questions presuppose a concept of the ego which is derivative from my proximity to the Other. In this way Levinas makes more precise the goal, announced in 1951, of having ethics supplant ontology as first philosophy. In *Otherwise than Being* it is pursued largely by exploring the realm of selfhood that previous philosophy has left unmined.

There is some controversy as to whether the analyses of *Otherwise than Being* supplant or only supplement those found in *Totality and Infinity*. Certainly there are differences. The emphasis on separation in the earlier works gives way to an account of proximity which locates at the heart of selfhood a certain restlessness unconcerned with reciprocity. The foundational narratives of *Totality and Infinity*, reminiscent of social contract theory, that describe the first encounter that an I has with an Other, give way in *Otherwise than Being* to structures that are said to be 'older even than the a priori'. There is no longer an attempt to coordinate the ethical and the ontological: the former interrupts the latter. If *Totality and Infinity* describes how the ego is put in question by the Other, *Otherwise than Being* puts the concept of the ego in question, not by denying the substantiality of the subject as other continental philosophers have done, but by locating alterity within selfhood so that I can be said to be 'in myself' only through the others. Levinas himself has indicated that it was his rejection of the ontological language of *Totality and Infinity* that led to *Otherwise than Being*, but he did not renounce the earlier analyses, which he has often repeated in essays that postdate *Otherwise than Being*.

According to Levinas, the needs of the Other make demands on me that are impossible for me to fulfil. Most traditional ethical systems reject any such multiplication of my responsibilities on the grounds that it is destructive

of good conscience. Traditional ethical philosophies also have no place for Levinas' insistence that one is responsible even for what took place before one was born. They would see Levinas as extending the concept of responsibility to the point that one's sense of responsibility for what is within one's power is diminished. However, Levinas regards all such attempts on my part to limit specifically my responsibility as a reduction of ethics to justice. It amounts to limiting the demands I make on myself to the same standards that it is reasonable and proper for me to apply to others. From Levinas' perspective, what ordinarily passes for ethics is an evasion of the ethical, but he is well aware that it would be impossible to live constantly according to his conception of ethics. His account of the face-to-face is a description of being obsessed by the Other that amounts to a psychosis. Even though in interviews Levinas has questioned whether his work is properly called ethics, his questioning of the ontological basis of Western philosophy has succeeded in raising the question of whether what passes for ethics in that tradition has yet got to the bottom of the call to be ethical.

ROBERT BERNASCONI

List of works

Levinas, E. (1930) *La Théorie de l'intuition dans la phénoménologie de Husserl*, Paris: Felix Alcan; trans. A. Orianne, *The Theory of Intuition in Husserl's Phenomenology*, Evanston, IL: Northwestern University Press, 1973.(The first major study of Husserl in French, still valued as an introduction to his work.)

Levinas, E. (1935) 'De l'evasion' ('Evasion'), *Recherches Philosophiques* 5: 373-92.(Reissued under the same title in 1982 by Fata Morgana with an introductory essay and notes that extended it to a 121-page book.)

Levinas, E. (1947a) *De l'existence à l'existant*, Paris: Vrin; trans. A. Lingis, *Existence and Existents*, The Hague: Martinus Nijhoff, 1978.(Studies of fatigue, indolence, effort and horror that mark the beginning of his attempt to leave the climate of Heidegger's thought without regressing to a pre-Heideggerian position.)

Levinas, E. (1947b) 'Le temps et l'autre', in *Le Choix - le monde - l'existence*, ed. J. Wahl, Grenoble and Paris: Arthaud; trans. R.A. Cohen, *Time and the Other*, Pittsburgh, PA: Duquesne University Press, 1987.(The translation adds two more recent essays, including 'Diachrony and Representation' (1982), which is especially important.)

Levinas, E. (1951) 'L'ontologie, est-elle fondamentale?', *Revue de Métaphysique et de Morale* 56: 88-98.(A translation can be found in *Levinas: Basic Philosophical Writings* (1996).)

Levinas, E. (1961) *Totalité et infini*, The Hague: Martinus Nijhoff; trans. A. Lingis, *Totality and Infinity*, Pittsburgh, PA: Duquesne University Press, 1969.(The classic work that lays out Levinas' basic positions on ethics and alterity.)

Levinas, E. (1974) *Autrement qu'être ou au-delà de l'essence*, The Hague: Martinus Nijhoff; trans. A. Lingis, *Otherwise than Being, or Beyond Essence*, The Hague: Martinus Nijhoff, 1981.(Levinas' most important and most sophisticated work but also the most difficult.)

Levinas, E. (1982a) *De Dieu qui vient à l'idée*, Paris: Vrin.(The most important of over a dozen collections of essays. It includes the classic 'God and Philosophy'.)

Levinas, E. (1982b) *Éthique et infini*, Paris: Fayard; trans. R. Cohen, *Ethics and Infinity*, Pittsburgh, PA: Duquesne University Press, 1985.(Interviews with Philippe Nemo that serve as an excellent introduction.)

Levinas, E. (1988) *À l'heure des nations*, Paris: Minuit; trans. G.D. Mole, *In the Time of the Nations*, London: Athlone Press, 1994.

Levinas, E. (1990) *Nine Talmudic Writings*, trans. A. Aronowicz, Bloomington, IN: Indiana University Press. (Contains translations of *Quatres lectures talmudiques* (1968) and *Du sacré au saint* (1977).)

Levinas, E. (1996) *Levinas: Basic Philosophical Writings*, ed. A. Peperzak, R. Bernasconi and S. Critchley, Bloomington, IN: Indiana University Press.(A collection of Levinas' most important philosophical essays with introductory essays and notes added by the editors.)

Lévi-Strauss, Claude (1908-)

Lévi-Strauss is one of the outstanding figures of mid-twentieth century intellectual life, influential far beyond the boundaries of France or the French language, and he has continued to write new work well into his eighties. His name is linked above all to the structuralist movement, of which he has been probably the most single-minded and unwavering exponent, and he was one of the key figures in the experiment of applying the insights of linguistics to the material of the social sciences. Through his work, public recognition of the discipline of anthropology grew dramatically to become an important element in discussion of philosophical issues.

The philosophical environment in France, in which structuralism developed and against which it reacted, was that of Sartrean humanism. In contrast to the existentialist emphasis on individual subjectivity, structuralism expected to find objective solutions to problems in the study of human beings. It was a form of intellectual modernism, a radical break with previous theoretical models and philosophical traditions, symptomatic of post-war optimism for the global applicability of science. It was hostile to metaphysics, bracketed the search for truth and was indifferent to the human subject. And, in contrast to Bergson's emphasis on continuity and flux, structuralism took discontinuity as its founding principle.

1 Life

Claude Lévi-Strauss was born in 1908. His grandfather was the rabbi of Versailles and his father was a painter. After studying philosophy in Paris he went to the new university of São Paulo in 1934 as professor of sociology, and during his five years in Brazil spent some time travelling in the interior. Returning for military service in 1939 he escaped to New York after the fall of France, and spent most of the Second World War lecturing at the New School for Social Research. Two decisive influences on his intellectual development derive from this period: first, contact with Roman Jakobson and second, exposure to the empirical approach of US anthropology. Since then he has lived and worked in Paris, mostly at the Collège de France, and became a member of the Académie française in 1973.

2 The impact of structural linguistics

Attending Jakobson's lectures on linguistics and phonology in 1942 seems to have been a revelation for Lévi-Strauss. Structural linguistics taught him that 'instead of being led astray by a multiplicity of terms, one should consider the simplest and most intelligible relationships uniting them' (1983, ch. 9: 139). The idea that the phoneme has no intrinsic meaning, but only acquires significance in relation to other similar elements, became the heart of his new approach to anthropological debates. The structural study of phonology emphasized two further principles that were to become fundamental to his work: the importance of unconscious mental activity in the production of language, and the fact that language is organized through discontinuous elements linked in particular ways.

Many commentators have linked Lévi-Strauss' structuralism directly to Saussure. However, it is clear from more recent writings that Lévi-Strauss' source of inspiration was Jakobson's interpretation of Saussure. His own use of Saussure was highly selective, emphasizing above all the arbitrary nature of the linguistic sign, the synchronic basis to linguistic analysis, and the syntagmatic and paradigmatic relations that link linguistic signs. These involve relations of contiguity and similarity, analogous to Jakobson's distinction between metonymy and metaphor (see Structuralism in linguistics).

3 The study of kinship

During this same period, Lévi-Strauss engaged in an extensive study of the ethnological literature, seeking to uncover the 'simplest and most intelligible relationships' that united all the wealth and diversity of the ethnographic record. His first area of interest was kin relations, a topic that linked him directly to the central concerns of anthropology and to Durkheim (§3) and Mauss' theories of social solidarity. His first book, *The Elementary Structures of Kinship* (1949), brought these different strands together in a vast synthetic work that transformed the way that anthropologists understood kinship.

Lévi-Strauss proposed that the incest taboo is analogous to the phoneme, in that it has no meaning of its own but

serves to link two domains. This is achieved by the exchange of women between kin-groups, which constitutes the origin of culture and is its ongoing pre-condition. Like all his work, his theory of kinship is controversial, but many of its insights have become canonical.

4 Totemism and *The Savage Mind*

Kinship led Lévi-Strauss to the theme of totemism and systems of classification, and the application of his theories to more obviously mental phenomena. He took issue with the argument, associated particularly with Lucien Lévy-Bruhl, that the thought processes of primitives are based on entirely different principles to our own. In *The Savage Mind* (1962) he showed how all human cultures employ the same principles to define and order their environment. In fact, 'the savage mind' is an unfortunate - if by now well-established - translation of *La pensee sauvage*, since the English expression implies that he is referring to some distinctive primitive mentality. All humans are alike, in his view, in the way that we rely fundamentally on sensual perception for our systems of classification and knowledge - the 'science of the concrete'. At the same time, primitives are just as capable of abstract thought as we are.

However, Lévi-Strauss does specify the significance of different levels of abstraction, expressed through his well-known contrast between the *bricoleur* and the engineer. The French *bricoleur* is a sort of jack of all trades, who puts things together with whatever materials lie to hand. Most of us for most of the time are *bricoleurs*, close to percepts, using the science of the concrete. By contrast, the 'engineer' operates at 'one remove' from observable properties, constructing concepts appropriate for the use to which they will be put.

In practice, Lévi-Strauss has devoted his life's work to studying the thought principles of *bricoleurs* rather than engineers. But implicitly his own work stands as perhaps a key example of what he means by the engineer. He believes that he has identified the abstract principles that underlie all everyday human thought processes, and that anthropology is particularly suited to the attainment of knowledge because it seeks the 'view from afar'. No civilization can think of itself unless it uses others as a basis for comparison. The importance which he attaches to detachment and distance is also at the heart of his critique of Sartre published as the final chapter of *The Savage Mind*.

5 The science of mythology

The most extensive, and probably the best-known, part of Lévi-Strauss' work is dedicated to the understanding of myth, another manifestation of the 'science of the concrete'. While myth uses the material world as means of thought, it is free from the constraints of material reality. Lévi-Strauss contrasts his own approach to myth with that of Jung, who in Lévi-Strauss' view erred by assuming that myths have stable meanings and a referential function. For Lévi-Strauss, the search for the manifest meanings of myths misses their true nature, which lies beneath the multifarious and often fantastic surface phenomena, where the human mind (*l'esprit humain*) rehearses unceasingly the opposition between nature and culture and the contradictions of human life, without offering a clear explanation or meaning.

Lévi-Strauss' approach to the analysis of myths discounts their narrative form in favour of identifying their component parts, in the spirit of the Russian Formalism of his mentor Jakobson, and others such as Vladimir Propp, author of the hugely influential *Morphology of the Russian Folk Tale*. To identify these discontinuous elements Lévi-Srauss in *The View From Afar* coined the concept of the 'mytheme' analogous to the phoneme - 'a purely differential and contentless sign' (1983: 145). These elements are linked by the principles of metaphor and metonymy, of syntagmatic and paradigmatic relations. The language of myths is, then, an unconscious one, rather similar in his view to that of the genetic code: far from being the consciously-created stories of individual narrators, 'myths operate in men's minds without them being aware of the fact' (*The Raw and the Cooked* (1964: 12).

As such, each myth is connected to others, not only within the same language and cultural group, but beyond that to myths recorded for far-away groups speaking different languages. In his four volume *Mythologiques* 1964-71) he traces mythical themes and structures from one end of the American continent to the other. Crucial to this enterprise is the concept of transformation: in Lévi-Strauss' hands this is a relatively static concept, referring typically to the way that myths are related through inversion, that is, the underlying structure of two apparently

divergent and unrelated myths contains the same elements, but arranged in a different way.

His concept of transformation - a formal rather than a dynamic one - typifies his temporal concepts. Synchrony, the suspension of temporal movement, was a guiding principle for structuralism, and for Lévi-Strauss synchrony expresses a core value. Music has provided a significant analogy, for example in *The Raw and the Cooked* where the temporal unfolding of music (and by analogy the narrative unfolding of myths) is subordinate to the structural principles which unite a piece of music, and link it to other pieces.

6 Lévi-Strauss' theory of knowledge

True knowledge for Lévi-Strauss arises from contemplation. In this respect pre-literate societies, where mythical structures are found in their purest form, come closest to his ideal. They typically strive to negate the effects of history and change, in contrast to the modern world where these are celebrated as good in themselves. In many of his writings Lévi-Strauss emphasizes the unity of the human mind across time and culture, stressing the similarity of purpose and method between our distant ancestors who domesticated animals and plants and our own scientific concerns (especially *Structural Anthropology II* (1973, ch.18). In others he implicitly attributes cognitive superiority to the 'engineer' or indeed to the anthropologist. And yet in other respects it is clear that he admires the disappearing world of the primitives who understood the significance of synchrony.

His passionately argued belief that the primitives were as much intellectuals as we are represents a grand if flawed attempt to create a unified theory of the human mind based on detailed comparative work. It derives from a model of human nature which is grounded in intelligence (in contrast to other models which privilege the emotions and instincts, or self-interest and strategy). However for all his intellectualism, many of Lévi-Strauss' ideas have stood the test of time more for their aesthetic insights and intuitions, than for his theoretical elaborations. As a number of commentators have pointed out, the whole elaborate edifice of structural linguistics conceals as much as it elucidates his aims and methods. He is closer to literature, to music, and above all to painting, and in a late work comments that 'the suppression by chance of ten or twenty centuries would not appreciably affect our knowledge of human nature. The only irreplaceable loss would be the works of art' 1993: 176).

In his analysis of actual myths, Lévi-Strauss' rigorous formalism and implicit reductionism is complemented by an extraordinary grasp of empirical detail and a sensitive attention to the distinctive properties - visual, tactile, olfactory, chemical, aural, functional - of whatever it is that the myth purports to be about. This attention to detail partially undermines the importance which he himself attaches to the Saussurean principle of the arbitrariness of the sign. It was clearly an important notion which enabled him to get away from the referential functions of language, but it should not blind us to the fact that most of the mythical signs which he has devoted the last thirty years of his life to analysing are not arbitrary in the Saussurean sense at all.

Lewis, Clarence Irving (1883-1964)

The American philosopher C.I. Lewis held that in all knowledge there are two elements: that which is presented to sense and the construction or interpretation which represents the creative activity of the mind. Contrary to Kant, Lewis claimed that what is fixed and unalterable is not the structure that we bring to the sensibly presented, but rather the sensibly presented itself. The categories that mind imposes do not limit experience; they determine the interpretation we place upon experience, and if too much of experience eludes our categorizations, new ones should be established. It is pragmatically necessary that we create interpretive structures which will work in getting us around in sensory experience. This important and novel doctrine, Lewis' 'pragmatic a priori', emerged through the development of ideas which took root during his study of logic. The problems of choosing among alternative logics led him to assert the need for pragmatic criteria. The way we conceptually structure or categorize experience answers to pragmatic criteria of purposes, intents and interests. Only within a context defined by a priori categorizations can empirical judgments be made. These empirical judgments proceed from apprehensions of the sensibly presented to assertions of objectivities. Moral judgments require both judgments of good and decisions of right. Judgments of value are tied to qualitative satisfactions disclosed in experience and are empirical claims. Decisions about the morally right are based on imperatives of reason.

1 Life

Clarence Irving Lewis, an American philosopher who focused on epistemology, logic and ethics, was born in 1883 in Stoneham, Massachusetts, and died in Menlo Park, California, in 1964. He was educated at Harvard, receiving his BA in 1905 and his Ph.D. in 1910. After receiving his Doctorate, he taught at the University of California from 1911 to 1920, and then at Harvard, where from 1930 he was the Edward Peirce Professor of Philosophy until his retirement in 1953.

2 Logic and the a priori

Lewis' important and novel doctrine of the pragmatic a priori emerged through the development of ideas which took root during his study of logic. This work in logic, combined with a healthy respect for Kantian epistemology, a long exposure to Roycean idealism and an appreciation of certain basic tenets of classical American pragmatism, produced the context from which the pragmatic a priori, the vital core of Lewis' conceptual pragmatism, took shape (see Royce, J. §3; Pragmatism §2).

Lewis spent many years in the study of logic, disturbed mainly by the conception of implication developed in the extensional logic of Whitehead and Russell's *Principia Mathematica* (1910-13) (see Russell, B.A.W. §3; Whitehead, A.N. §2). This 'material implication' deviated strikingly from the ordinary sense of implication. According to it, a false proposition implies any proposition, while a true proposition is implied by any proposition. The problem, Lewis held, lay in the fact that the logic of propositions formulated in *Principia* is an extensional one, while ordinary deductive inference depends upon the meanings of the propositions used, and hence is rooted in intensional relations. The solution to this problem led Lewis to the development of the system of strict implication in symbolic logic and carried him beyond logic into the field of epistemology and the development of a detailed theory of meaning and analyticity.

A second type of issue, arising out of the entertainment of the possibility of an alternative to the logic of material implication, led to his interest in the existence of various types of alternative logics such as many-valued logics (see Many-valued logic §1; Modal logic §1). It also carried him beyond logic to the development of a theory of knowledge asserting the free creation of and pragmatic selection among various possible a priori conceptual schemes as tools of interpretation of experience.

Lewis held that the behaviour of symbolic systems operates in the same way as the behaviour of the human mind, that there is nothing in them which we have not put in ourselves, but that they teach us the meaning of our commitments. Thus, a priori truth is independent of experience because it is purely analytic of our conceptual meanings. The line between the a priori and the a posteriori, then, coincides with the divisions between the conceptual and the empirical, between the contributions of mind and what is given in experience, between the analytic and the synthetic.

3 Meaning and analyticity

According to Lewis, the meaning or deductive significance of a proposition, which can be thought of as a kind of term, coincides with the intension of the proposition, in the sense that whatever is deducible from the proposition is contained in its intension. A proposition signifies a state of affairs. A state of affairs is not a chunk of reality to be denoted, but rather includes all that the assertion of the state of affairs as actual implies, and only what it thus implies.

All real definitions specify intensional modes of meaning. What Lewis here means by a real definition is neither symbolic convention nor dictionary definition, but rather an explicative statement which relates a meaning to a meaning. There are two types of meanings related in such real definitions: linguistic meaning and sense meaning. Linguistic meaning is the pattern formed by the relation of a term or proposition to other terms or propositions. Sense meaning is the criterion in mind which determines the application of the term or proposition; it is the criterion by which what is meant is to be recognized.

Analytic truths state relations between sense meanings and not merely between linguistic meanings. Lewis sets out to undercut the conventionalist position that analytic truth expresses nothing beyond what is or can be determined by the language system which embodies it. Although he holds that there are conventional elements in the choice of symbols, in the assignment of the symbols to the meanings and in the choice of the meanings to be considered, he insists that the interrelation of the meanings is neither linguistic nor arbitrary. The analyticity of the linguistic meaning is determined by the fixed intensional relationships of sense meanings.

Lewis' position reveals both a sympathy towards, and yet sharp criticism of, Kant's epistemology. This critical appreciation of the insights of Kant is nowhere more in evidence than in his rejection of Kant's synthetic a priori, a rejection based directly on Lewis' own use of the Kantian concept of schematism (see Kant, I. §7). A sense meaning as a schema is a rule or prescribed routine and an imagined result of it which will determine the applicability of the word. By this means Lewis proposes to solve the epistemological problem of the nature of the necessity of analytic truth and how we know such necessity. We perform an experiment in imagination. We know that 'All squares are rectangles' because in envisaging the test which a thing must satisfy if 'square' is to apply to it, we observe that the test it must satisfy if 'rectangle' is to apply is already included. Both Lewis' theory of meaning and his notion of the test schema reveal that his theory of analyticity is basically one of inclusion or containment.

Empirical meaning, then - meaning as a criterion in mind by reference to which the applicability of a term or the believability of an empirical statement is to be attested in experience - is a mode of intensional meaning. Lewis emphatically rejects as epistemologically untenable the nominalist conception that individuals are the first knowables and are primitively determinable by ostensive reference. It is only by reference to intensional meaning as criterion in mind by which one applies or refuses to apply a term that denotation is possible.

4 The a priori and pragmatic considerations

The truth of any empirical generalization is determined by the relationship of a conceptual scheme to given experience, and remains true, relative to that scheme. Empirical truth does not literally change, nor are contexts of interpretation proven false. Rather, conceptual schemes which do not work adequately as interpretive contexts are replaced by others. The sense in which truth is 'made by the mind' and is 'relative to human interest and purpose' is the sense in which we choose the interpretive structures by which we prescribe the outlines of realities of particular types and in so doing set the context for the discovery of empirical truth. However, the analytic or a priori truth contained in the interrelationships of the interpretive structures is subject neither to the contingencies of experience nor to the whims of convention; rather, it is eternally true. Such truth is not material truth but formal truth or validity.

Lewis holds not only that our choice of an analytic, a priori conceptual scheme is conditioned by experience in that it is based on pragmatic considerations operative in the light of past experience, but also that the logic which the conceptual schemes apply and by which they are interrelated is itself based on pragmatic considerations and hence is, in the last analysis, conditioned by experience. Lewis' pragmatism runs quite deep. Humans, for Lewis, are essentially acting beings. Meanings which mind entertains, the logic which explicates such meanings, and mind itself emerge from behavioural responses to the environment in which humans find themselves. Our ways of

behaving towards the world around us which are made explicit in our accepted logic are those which have lasted because they work. The final ground, even of the validity of the principle of consistency as well as the validity of ordinary inference, is firmly rooted in a pragmatic, evolutionary-based direction of successful activity. The principle of consistency, and that ordinary inference which explicates our meanings in accordance with the principle of consistency, is rooted in a ‘pragmatic imperative’: if it is rejected, then thought and action themselves become stultified.

Lewis’ concept of the a priori occupies a unique position in the debate concerning the nature of a priori knowledge and the very possibility of an analytic-synthetic distinction. Drawing on a fundamentally Kantian scheme made responsive to the insights of American pragmatism and adapted to fit the needs of contemporary logic, Lewis has established an a priori which is coextensive with the analytic, yet which cannot be said to be empirically vacuous. It both arises from experience and has possible reference to experience.

5 Empirical knowledge

Lewis distinguishes three levels of empirical statement which enter into the formulation of empirical knowledge: expressive utterances, terminating judgments and objective beliefs.

Expressive statements, or the expressive use of language, signify appearances or indubitable content. They neither assert nor deny any objective reality of what appears; neither do they predict anything. Because they are confined to description of the immediate content of presentation, they cannot be in error. The immediate content is not judged, it is ‘had’.

Terminating judgments state the prediction of a particular passage of experience. They find their cue in what is given, but state something taken to be verifiable by some test which involves a way of acting. Since terminating judgments are expressed in expressive language, if the judgment is true, its truth is known with certitude, since there is no further means to bring it into question.

Finally, there are non-terminating judgments or judgments of objective fact. Such judgments express objective beliefs which can never be completely verified but are always further verifiable. Because such beliefs can never be completely verified they are probable, not certain. Non-terminating judgments are expressed in the form, ‘If this is a physical object O, then if S appearance and action A occur, then in all probability E appearance will occur’. The major, or first, implication relation of the non-terminating judgment expresses the logical entailment of strict implication. The second implication relation of the non-terminating judgment, or in other terms the implication relation holding within the terminating judgment, expresses what Lewis calls ‘real relations’. These real relations are causal relations involving contrary-to-fact conditionals and probability relations.

Our physical-object concepts embody habits of belief, and a habit is not just a collection of possible appearances and responses to these appearances; it is a rule of organization of possible appearances and possible responses which, in its very being as a rule, contains the possibility of generating more explicit relationships than can ever be enumerated. The meaning of objectivity is something over and above a collection of related appearances, and this meaning is supplied by the fixed rule of organization. Thus, though a physical-object statement is confirmable by verifying experiences, it is not reducible to or totally translatable into the verifying experiences.

Perhaps no single aspect of Lewis’ philosophy has been subject to more frequent and diverse attacks than his concept of the given element in experience. He expressed an ongoing frustration that his understanding of the given had been so misinterpreted over the years, stressing that the point he is trying to make is so obvious that he wonders how anyone could contest it. If there is nothing given, there would be no content for thought, nor could there be success or failure in action, and prediction would be incomprehensible. His emphasis on the given, as he himself stresses, is not a foundationalist or phenomenalist concern about data from which we build up a world of objects, but a pragmatic concern with the way in which we proceed to verify our beliefs. If nothing is to be counted as certain, then probable knowledge is not possible, for knowledge would be merely ‘probably probable’. The probability involved in our predictive claims must be founded in something that is not subject to probability claims. The sensibly presented, as apprehended, is a ‘taken’, but is pragmatically certain in that it serves as the test for our various claims, but cannot itself be tested since it makes no reference to future experience.

6 Ethical writings

Lewis' moral theory is an extension of the view developed in his philosophy of knowledge. There are two dimensions involved, a given element and a priori categorization. Lewis rejects the sceptical view that evaluations are emotive and unverifiable, and asserts instead that they are a species of empirical knowledge.

What is intrinsically valuable or valuable for its own sake is the quality of an experience. An experience further has contributory value through the contribution it makes to the full quality of the life of the person having it. These are reported in expressive terms, leading to decisively verifiable terminating judgments, and moving on to objective probability statements which are judgments of extrinsic value and attribute a property of value to an objectivity of some kind. Extrinsic values may be inherent or instrumental. The former lead directly to experiences which are intrinsically valuable, while the latter arise as means to an end that is inherently valuable. Judgments about right and wrong are not empirical, but rather are determined by principles which in their prescriptive character refer to values. The fundamental rational imperative is to think and act in a way that one will not later regret. Rationality requires that actions must be in accordance with objective knowledge of relationships productive of value experience in the future for all, rather than in accordance merely with the felt quality of one's immediate experience.

Lewis, Clive Staples (1898-1963)

C.S. Lewis was a British religious writer. Originally trained as a philosopher at Oxford, he combined literary scholarship and the writing of fiction with clear and persuasive argumentation for traditional Christianity. His religious works continue to be best sellers, and much of his writing is directly or indirectly of philosophical interest. For the non-philosophical public, he probably remains the best representative of the position that religion is more rational than any alternative. Lewis is regarded by his admirers as more than a philosopher: in the words of Walsh (1949), he is the twentieth century's 'apostle to the skeptics'.

The most interesting of Lewis' arguments for the existence of God is one sometimes called 'The Mental Proof'. One way of getting a preliminary insight into this argument is to ask whether nature is a product of mind, or mind is a product of nature. If God created nature, as Christians believe, then nature is understandable by reason because it is a product of reason. It sounds superficially plausible to say that if mind were the product of nature, nature would be understandable by mind as well. But in fact, there is no acceptable general rule that a product can understand what produces it.

Furthermore, if nature is seen as non-rational, as without intelligence or purpose of its own, a special difficulty arises. One thing may produce another by design, by chance or by the unfolding or development of some process already inherent in the producing agent. But if nature is without intelligence or purpose, it cannot produce mind by design, nor can it produce it as the unfolding or development of something already there. So a mindless nature can produce mind only by chance. But if mind is only a chance product of nature, how can we trust our reasoning powers, how can we expect our minds to give us the truth about anything? In fact, Lewis slightly overstates his point in the first edition of *Miracles* (1947): he says that when we find that a position has been caused by non-rational factors, such as chance, we should immediately dismiss it.

In the same work, Lewis also makes some incisive criticisms of Hume's arguments against miracles, that 'there must be a uniform experience against every miraculous event'. First, says Lewis, Hume begs the question by assuming at the outset that there is 'uniform experience' against miracles. Second, the question of whether the universe is such as to allow miracles is not a question that can be settled just on the basis of experience. The most compelling reason for the uniformity of nature is that nature was the result of design by an intelligent being. And if we admit that, then the being who designed the laws of nature can suspend them (see Miracles).

A number of Lewis' arguments for God exhibit the same pattern: a fact of experience is vividly described, then explained by Christian theism. For example, our experience of recognizing the claims of morality and at the same time failing to meet those demands is explained by a God who is the source of morality and a human race estranged from that God (see Religion, history of philosophy of §5). Or our experience of longings which can be satisfied by no finite object, but which seem to indicate a real need calling out for a real object can be best explained by a God who is our final good. On Lewis' view, attempts to explain these facts of our experience without bringing in God lead to our explaining them away.

Lewis also gives an argument which has been called the 'Lewis trilemma' (see 'The Shocking Alternative' in *Mere Christianity*). He argues that the claim by Jesus to be God cannot be separated from the New Testament accounts of his life and work; for example, his claim to forgive sins on his own authority could only be made by God. Lewis then poses three alternatives: Liar, Lunatic or Lord. But Jesus is recognized by almost everyone as a great moral teacher: could such a teacher lie or be subject to an insane delusion? Lewis concludes that seeing Jesus *only* as a great moral teacher is not a possibility left open by the evidence; he must be more or less than this.

Lewis, David Kellogg (1941-)

David Lewis has made extremely important and influential contributions to many topics in metaphysics, philosophical logic, the philosophy of science, the philosophy of mind, the philosophy of language, the philosophy of probability, rational decision theory, and ethics and social philosophy. His work on counterfactuals and the philosophy of modality has been especially influential.

1 Life

David Kellogg Lewis was born on 28 September 1941 in Oberlin, Ohio, where his father taught government at Oberlin College. His mother, a historian, did some teaching for the college, but did not hold a regular appointment. Lewis attended Swarthmore College, from which he received a BA in philosophy (high honours) in 1962. His postgraduate studies were at Harvard, where he received an MA in 1964 and a Ph.D. in 1967. He served as Assistant Professor of Philosophy at UCLA from 1966 to 1970, and has since taught at Princeton. Lewis has for many years had a special relationship with Australia, where he has spent two or three months of every year, usually without formal academic appointment, since 1979. In September 1995 he was awarded an honorary doctorate by the University of Melbourne.

2 Counterfactual conditionals

In 'A Theory of Conditionals' (1968), Robert Stalnaker proposed the following semantical analysis of counterfactual conditionals: the counterfactual having antecedent *p* and consequent *q* (' $p \rightarrow q$') is true if and only if either *p* is impossible or *q* is true in the possible world closest to actuality in which *p* is true (or '*q* is true in the *p*-world closest to actuality'). (Stalnaker's analysis assumes that for any possible world *w* and any possible proposition, there is a unique world that is the closest world to *w* in which that proposition is true.) One important consequence of this analysis is that any sentence of the form '($p \rightarrow q$) or ($p \rightarrow \mathrm{not}\text{-}q$)' - for example, 'If Lincoln had not been assassinated, Hitler would (still) have invaded Poland in 1939, or else if Lincoln had not been assassinated, it would not have been the case that Hitler invaded Poland in 1939' - must be true. Lewis proposed an alternative analysis (1973a), which replaces the second disjunct of Stalnaker's analysis with the condition that there is some world *w* in which both *p* and *q* are true, such that every *p*-world at least as close to actuality as *w* is also a *q*-world.

On reflection, it seems that a counterfactual with a possible antecedent can be true even if there is no one closest world in which that antecedent is true. Suppose, for example, that there are two or more *p*-worlds that are equally close to the actual world, that all worlds closer to actuality than these are not-*p*-worlds, and that *q* is true in all these 'tied' *p*-worlds. It seems evident that $p \rightarrow q$ is true in this case. Lewis' analysis entails that a counterfactual is true if its antecedent and consequent are so related, and it avoids the counterintuitive consequence that '($p \rightarrow q$) or ($p \rightarrow \mathrm{not}\text{-}q$)' is a valid sentence-schema. For these reasons, it would be generally conceded that the logic of counterfactual conditionals that is generated by Lewis' semantics is much more intuitive than the logic that is generated by Stalnaker's semantics; most philosophers of logic, in fact, would probably be willing to say that Lewis' logic is the correct logic of counterfactuals.

There would be less agreement about the value of Lewis' informal, philosophical account of the basic items in his semantics: possible worlds and the 'closeness' relation. Lewis' idiosyncratic account of 'possible worlds' will be examined below. His account of 'closeness' is given in terms of comparative similarity - the concept illustrated by the comparison 'San Francisco is more like Boston than it is like Calcutta'. According to Lewis, the worlds closest to *w* are the worlds most similar to *w*. There has been considerable controversy about whether Lewis' truth-conditions for counterfactual conditionals are correct if closeness is understood in terms of similarity (see Counterfactual conditionals).

3 Modality: logic and ontology

Possible worlds are at the centre of Lewis' philosophy of modality. By the late 1960s it had become common to appeal to 'possible worlds' in discussions of modality. But many philosophers doubted whether any coherent philosophical sense could be made of the notion, particularly if each 'possible world' was to be associated with a well-defined set of individuals, those existing in it. By what criterion, it was asked, could an individual existing in

one world - say, Quine's 'as he is in the actual world' - be judged identical with an individual existing in some other world and having a set of properties very different from Quine's?

Some philosophers think of possible worlds as abstractions of some kind, perhaps as internally consistent and 'complete' stories, the actual world being the one that is true. Such philosophers reply to sceptics about the intelligibility of 'cross-world identity' in this way: Quine can 'turn up in' various stories, stories both true and false, even if the false stories ascribe to him properties very different from the properties ascribed to him by the true stories. According to Lewis, however, a world is no mere story. A world is a spatiotemporally connected and closed object (or at least an object closed under some relations that, like spatiotemporal relations, are 'external'). For Lewis, a world is a very substantial thing indeed: our cosmos is one of them, and the others differ from it 'not in kind but only in what goes on at them'. A 'possible object' like Quine is 'in' a world if it is a part of it, and no possible object is a part of more than one world. Lewis' answer to the sceptics is therefore that Quine is simply not identical with anything in any other world.

The totality of worlds, Lewis maintains, is a 'logical plenum'; there is a world for every possible arrangement of things. (He is able to state this requirement without the use of any modal terms.) Although we rightly single out one member of the logical plenum as 'the actual world', there is in an important sense nothing special about it, for 'actual' is simply an indexical term like 'now' and 'here'.

Most philosophers have found the ontology that underlies Lewis' account of modality incredible. Many doubt whether there are any 'worlds' besides our own cosmos. Many wonder how Lewis knows that, even if there are other worlds, they are numerous and various enough to form a logical plenum. Many wonder why Lewis thinks that, given that there are all these 'worlds', they have anything to do with modality, or why each of them would be, as Lewis says each of them is, a 'way things could have been'. Another sort of worry, one that can perhaps be more profitably discussed, is closely related to Lewis' answer to the sceptics about cross-world identity: how can Lewis accommodate our convictions about 'modality *de re*'? No doubt Quine could have been a geographer. In the language of possible worlds, there is a world in which Quine is a geographer. But, the worrier points out, if Lewis is right, Quine is not in any world but our own (see De re/de dicto).

Lewis replies that, although Quine is not in any other world, there are people in some other worlds who play the same role in their worlds that Quine plays in his (our) world - who are the people in those worlds who are the most similar to Quine. If there are people in the world *w* who enjoy this status, they are the counterparts of Quine in *w*. (But since the question, 'Which things are most similar to *x*?' is a pragmatic question, one that can be answered in various ways depending on one's interests, there is no unique 'counterpart relation' - no one relation that is expressed by '*x* is a counterpart of *y*'.) Lewis analyses modal statements *de re* by reference to the counterparts of the *res* they concern: to say that Quine could have been a geographer is to say that he has a counterpart who is a geographer. This analysis has been disputed on the ground that Quine's counterparts are not, after all, Quine; therefore, it is urged, no statement about their features could be equivalent to any statement about what he could have been. Lewis replies that the property 'could have been a geographer' is the property 'has a counterpart who is a geographer'. If, therefore, Quine has a counterpart who is a geographer, Quine has the property 'could have been a geographer'. But this reply requires a qualification. Since there is no one counterpart relation, there is no one property that is expressed by 'could have been a geographer'. Whether we are willing to say that Quine could have been a geographer is, in consequence, a function of the interests that we bring to our discussions of how Quine could have been different.

In 'Counterpart Theory and Quantified Modal Logic' (1968), Lewis presents his thoughts about counterparts and modality in a very general form. He presents an extensional first-order language whose primitive nonlogical vocabulary comprises only predicates - for example, '*x* is a possible world', '*x* is a counterpart of *y*' and so on - and he embodies his theory of counterparts ('Counterpart Theory') in eight axioms stated in this language. He presents an algorithm for translating sentences of quantified modal logic into this language. He goes on to make some illuminating observations about quantified modal logic by showing that certain 'famous' problematical sentences in the language of quantified modal logic correspond under the translation algorithm to theorems, and certain others to non-theorems, of Counterpart Theory; he shows that if various formal restrictions were placed on the counterpart relation - restrictions that would in his view be arbitrary - the theorems that would thereby be added to Counterpart Theory would be translations of certain of the 'famous' sentences of quantified modal logic.

He shows, finally, that, although all sentences in the language of quantified modal logic can be translated into his extensional language, the converse does not hold. The latter is therefore a richer language: it has all the expressive power of the language of quantified modal logic and more besides.

An important feature of Lewis' account of modality is that, unlike most other accounts of modality, it is reductive. If Lewis is right, modal terms can be eliminated from our discourse in favour of spatiotemporal terms, 'part', and an indexical term like 'we'. (It is, moreover, arguable that if one accepts Lewis' modal ontology, one need include in one's ontology no non-individuals, but sets ultimately grounded on individuals. Propositions, for example, can be identified with sets of worlds, and properties with sets of the things in them.) Whether or not those who find Lewis' modal ontology incredible are right so to regard it, it is undeniable that a lot more can be done with it than with any other modal ontology. We have seen that it provides a reductive analysis of modality. We have not been able to discuss its astounding successes - granting only its truth - in dealing with a very wide range of philosophical problems. (The philosopherJohn Perry has remarked that it 'goes through philosophical problems the way a McCormick reaper goes through wheat'.) Perhaps the same feature of the ontology - the vast range of spatiotemporal objects it assumes - accounts both for its extraordinary power and the 'incredulous stares' that have been so often directed at its inventor. Lewis does not dispute the validity of the maxim 'Entities are not to be multiplied beyond necessity', but he insists that, once the content and consequences of a theory have been made as clear as they can be, whether the entities assumed by that theory lie inside or outside the bounds of 'necessity' is a matter of individual, subjective judgment.

Li

Li *means 'pattern' or 'principle', and as a verb can also refer to the creation of orderly pattern. Mencius believed that the human heart-mind had an inherent taste for and attraction to such 'good order'. His contemporary, Zhuangzi, was the first to use* li *to refer to an underlying normative 'pattern' structuring and giving order to the entire world. This sense in turn influenced the Confucian thinker Xunzi, who employed and developed the concept to express his understanding of Confucianism. Certain Buddhist thinkers used the notion of* li *to describe first 'emptiness' and later 'Buddha-nature', the common underlying characteristic of all phenomena. A version of this idea was adopted by neo-Confucian thinkers, who believed that while each thing manifested its own particular* li*, it also contained within it the* li *of all other things. Thus there is a profound metaphysical identity between self and world.*

The earliest and most basic sense of the character *li* ('pattern' or 'principle') is derived from the simpler graph which serves as its central component: a rectangular field divided into equal quadrants to form an 'orderly pattern'. As a verb, *li* has the related meaning of creating such a pattern, thus 'to set in good order'.

The Mohists were the first Chinese thinkers to use *li* with a distinctly philosophical sense (see Mohist philosophy). In the *Mozi*, *li* is used to mean 'good order' (for example, in Chapter 25 it is opposed to 'chaos'). In later Mohist writings, *li* means the principles governing such order and orderly principles of thought (Graham 1978: 192). These two senses of 'good order' are both present in *Mencius* 6A7, which claims that all human minds agree in approving of *li* (good order) and *yi* (what is right).

The most important and extensive early uses of *li* occur in the *Zhuangzi*. There, *li* appears both in the sense of the grand pattern underlying all phenomena and the individual instantiations of this pattern in discrete things. The *Zhuangzi* contains the first occurrences of 'heavenly principles', 'principles of the Way' and 'great principles', terms which connect the notion of 'pattern' to a greater cosmic scheme, lending it a wider metaphysical role and greater normative force. Being explicitly linked to 'Heaven' and the 'Way', *li* describes not only how things are but also how they should be. We also see several references to 'the principles of the myriad things' and in one case to 'the various principles of the myriad things', ideas that prove important in neo-Confucian thought (see Zhuangzi).

Xunzi was deeply influenced by these new senses of the term and incorporated them into his Confucian philosophy. Formally, his views are remarkably similar to those in the *Zhuangzi*, but their content - what he claimed to be the underlying pattern of the cosmos - was significantly different. Xunzi's ideal was a consciously anthropocentric harmony between human needs, desires and capacities, and Nature. Zhuangzi's vision lacked this human centre; he focused on 'heavenly principles', a term which does not appear in Xunzi's writing.

The view that *li* provides both a descriptive and normative pattern for individual things, while also being part of a larger cosmic pattern, gave rise to the idea that this larger pattern 'united' the various phenomena of the world. This idea can be found in Han dynasty texts such as the Huainanzi. It was most developed by thinkers such as Wang Bi, who speaks of 'ultimate principle' as an object of mystical contemplation and religious veneration. His contemporary Guo Xiang, who held similar views, also believed that the 'pattern' of the world was not the result of some predetermined plan but rather of 'spontaneous' processes. He insisted that the ultimate nature of the world was *wu* (non-existence) (see You-wu).

Chinese Buddhists adapted these later senses of *li* to express their own views. In the *Sutra in Forty-two Sections*, *li* is used to mean 'the true nature of reality', a full appreciation of which will result in complete enlightenment. Zhi Dun developed the equation of *li* with *wu* 'non-existence', understanding both in the Buddhist sense of 'emptiness'. Huayan Buddhists understood the 'emptiness' of reality - the lack of an independent, individual nature - to mean that all things are manifestations of a shared 'Buddha-nature'. Huayan works, such as the *Treatise on the Golden Lion*, argue that every 'phenomenon' contains within it all the various *li* (see Buddhist philosophy, Chinese; Buddhist concept of emptiness).

Like Huayan Buddhists, neo-Confucians believed that *li* describes the fundamental character of reality and that the spiritual life lies in grasping this shared, unifying principle. Cheng Yi was famous for the idea - derived from the

earlier Buddhist thinker Daosheng (d. AD 434) - that ‘principle is one; its manifestations many’. However, neo-Confucians believed that principle defined a classical Confucian world. Not unlike the earlier difference between Zhuangzi and Xunzi, their disagreement with the Buddhists turned largely on the content - not the formal structure - of their metaphysical views.

Zhu Xi believed *li* was logically prior to, though not actually separable from existing things. It lodged in *qi* (ether) to form actual things, riding it ‘as a person rides a horse’ (see Qi). While each thing contained all the myriad *li*, a given thing’s endowment of *qi* allowed only certain *li* to be manifested. Thus while in some deep sense things were the same, in the actual world each had its own particular (manifested) principle.

Neo-Confucians such as Lu Xiangshan and Wang Yangming took issue with this view. They feared that Zhu’s teachings, which described *li* as ‘above actual things and events’, would lead students away from their moral heart-minds and into quietistic contemplation. They argued that the mind did not contain but was itself principle. Later neo-Confucians such as Wang Fuzhi, Yan Yuan and Dai Zhen criticized these earlier thinkers for being infected with Daoist and Buddhist ideas. They argued for a return to the original sense of *li*: the ‘good and proper order’ inherent in the world (see Neo-Confucian philosophy §2).

Liber de causis

The Liber de causis (Book of Causes) is a short treatise on Neoplatonist metaphysics, composed in Arabic by an unknown author probably in the ninth century in Baghdad. Through its twelfth-century Latin translation, it greatly influenced mature medieval philosophy in the West.

Drawing heavily on the Greek Neoplatonist Proclus, the Liber de causis represents a development of late Neoplatonism along two lines. On the one hand, the author modifies and simplifies Proclus' theory of causes to accord more closely with the three-part division of ultimate causes advanced by the founder of Neoplatonism, Plotinus. On the other hand, the author introduces some of the metaphysical principles of Qu'ranic or biblical monotheism. The result is a metaphysically provocative reinterpretation of Neoplatonist thought which, because it seemed to accommodate Platonist philosophy to the medieval worldview, made the Liber de causis a natural source text for medieval philosophers.

1 Form, content and origin

The *Liber de causis (Book of Causes)* is presented *more geometrico*, that is, it proceeds by way of thirty-one discrete propositions, or theses (often amplified by corollaries), each accompanied by passages of interconnected supporting argumentation. Despite the systematic presentation, however, the work as a whole appears somewhat fragmentary, no doubt because the author was overly ambitious. It appears that he was trying to set forth, in outline, an entire theory of how the universe has been originated by a first cause (an entity consisting in pure goodness and perfect being) and how this cause's creative activity comports with the agency of other fundamental causes such as the Neoplatonist supramundane 'mind' and universal 'soul'. In the known Arabic manuscripts, the treatise is entitled either 'The Book of Aristotle's Exposition on the Pure Good' or 'Discourse on the Pure Good' (*Kalam fi mahd al-khair*); its designation as a *kalam* (discourse, discussion or spoken account) might be taken to indicate that the work is not actually intended to be a systematic treatise but, rather, a collection of teachings or meditations. Clearly, however, the work's shortcomings as a systematic treatise do not preclude a systematic philosophical intention on the part of its author or even a coherent underlying structure. Aquinas, in his *Super Librum de causis expositio (Commentary on the Liber de causis)* proposed an underlying structure in which every proposition has an identifiable expository function.

The *Liber de causis* was long thought, by Islamic as well as Western medieval philosophers, to be a work of Aristotle (see Neoplatonism in Islamic philosophy §1). In these philosophers' eyes, it filled out Aristotle's otherwise deficient account of the ultimate causes of the universe as presented in *Metaphysics* XII. Even before Aquinas demonstrated that the work was un-Aristotelian and indebted to Proclus' *Elements of Theology*, speculation had arisen about its authorship. Albert the Great's idea that the author might have been a twelfth-century Jewish writer in Spain, Abraham Ibn Daud, has until recently been considered a plausible hypothesis. Discoveries in the 1970s and 1980s, however, have given the controversy new direction. Very likely, the author of the *Liber de causis* was a Muslim or Christian thinker writing in the Near East, probably at the intellectual centre in Baghdad, in the ninth century (in any case, no later than the last quarter of the tenth century).

2 Philosophical context

Many historians of philosophy have seen the *Liber de causis* as merely an anonymous epitome of Proclus' *Elements of Theology* (see Proclus). Such views, however, miss the work's recourse to certain ideas of Plotinus, from which Proclus had departed. The author of the *Liber de causis* rejects Proclus' version of the doctrine of 'hypostases', the levels of reality posited by Neoplatonism as beyond the physical world, or causally prior to it (see Neoplatonism). Proclus argues that the fundamental causes of the universe consist in a complex system of hypostases arranged in a causal series, beginning with the first cause, the absolute One, and continuing to its ultimate effects in the material world through the intermediary hypostases of Finitude/infinity, Being, Eternity, Mind, Forms, Time, Soul and so on. By contrast, the *Liber de causis* re-affirms the simpler Plotinian causal series of three hypostases, the perfectly unified and simple first cause (the One), Mind and Soul.

What is at stake philosophically in the *Liber de causis*' simplification of the Neoplatonist series of hypostases and

the denial that there are intermediary hypostases between the first cause and the hypostasis of finite being as Mind? First, the *Liber de causis* breaks with Proclus' (and perhaps ultimately Plato's) principle that any common feature of things requires a special cause, or hypostasis, in which all the things possessing the feature participate. Second, the *Liber de causis* responds to one of the most basic problems of Neoplatonist metaphysics: if causal dependence involves a certain sort of similarity of effect to cause (participation of effect in cause), how can causes give rise to effects quite different from themselves? Locating a mediating factor between cause and effect in intermediate levels of reality, or hypostases, is a tendency that can be seen already in Plotinus. The *Liber de causis* represents a development of Neoplatonist metaphysics since it attempts to redress the extreme multiplication of hypostases found in later Neoplatonism.

The *Liber de causis* also exemplifies the creative interaction of Islamic and Christian thought with the legacy of Greek philosophy (especially Neoplatonism). This is illustrated by its presentation of the first cause as truly existent and as pure being (in contrast to the Neoplatonist characterization of it as in some sense beyond being), its philosophical refinement of the idea of creative causality, and its derivation from creative causality of a doctrine of universal providence. The treatise is apparently a product of the early, seminal stages of interaction between monotheistic speculation and Greek philosophy in the Islamic milieu, which took place in the latter half of the eighth century and through the ninth century (see Greek Philosophy: impact on Islamic philosophy). Since this formative period was a time in which Christian scholars and translators strongly influenced Islamic thought, the *Liber de causis* can also be said to have arisen out of early contact between Christianity and Islam.

3 A source for later medieval philosophy

Although further research will no doubt identify more echoes of the *Liber de causis* in the writings of later Islamic and Jewish medieval philosophers, its direct and definite influence on their work appears to have been relatively slight (exceptions are Ibn Sab'in, Al-Baghdadi and Ibn Ezra). Its substantial influence is to be seen more in its contribution to a general store of philosophical ideas than in its shaping of particular doctrines. In the Latin West, by contrast, the *Liber de causis* served as one of the most frequently used sources of Neoplatonist metaphysics and aided Christian medieval philosophers, even those strongly influenced by Aristotle, in building Platonist principles and ideas into the very foundations of their philosophical systems (see Platonism, medieval). Translated into Latin, probably around 1180 in Toledo by Gerard of Cremona, and known as *Liber Aristotelis de expositione bonitatis purae* or more simply as *Liber de causis*, the work became available to Western philosophers along with the bulk of Aristotle's works (see Translators). It made up part of the massive influx of Greek and Arabic learning into western Europe in the latter half of the twelfth century, quickly becoming a standard text; 237 extant Latin manuscripts have been identified. While its widespread acceptance was encouraged by the attribution to Aristotle, the *Liber de causis* was studied for its intrinsic interest. Its influence continued after Aquinas established its connection with the thought of Proclus.

The influence of the *Liber de causis* can be gauged in part by the fact that a high proportion of the major philosophers of the thirteenth and fourteenth centuries, as well as many minor figures, wrote commentaries on it. Twenty-seven commentaries from before 1500 have been identified. Written in a wide variety of genres, these commentaries include works by Roger Bacon, Albert the Great, Thomas Aquinas, Siger of Brabant, Henry of Ghent (attribution doubtful), Giles of Rome and others. Even more importantly, the direct influence of the *Liber de causis* shows in the frequent citations of it and the manifold adaptations of its doctrines found in major philosophical writings from the 1230s through the Renaissance.

For medieval philosophers, the *Liber de causis* represented not only a source of Neoplatonist ideas but also an adaptation of Neoplatonist metaphysics of the sort that they themselves were intent upon. Thus Aquinas, in his detailed and masterful commentary, is concerned to show how the *Liber de causis* differs from and is superior to its source in Proclus. Using a translation of the *Elements of Theology* made in 1268 by William of Moerbeke, Aquinas draws attention both to *Liber de causis*' affinities with Proclus' systematization of Neoplatonist metaphysics, and its divergences from it. In his analysis, he employs the metaphysical writings of the fifth-century Christian Neoplatonist Pseudo-Dionysius as a key to understanding the *Liber de causis* and also as a corrective when he thinks that the author has not gone far enough in re-working classical Neoplatonism. Affecting medieval philosophers' accounts of creation, divine nature and ontology, the *Liber de causis* provides them with particular ideas about creative and natural causation, the individuation of pure being and the constitution of finite being.

Liberalism

Liberal political philosophy explores the foundations of the principles most commonly associated with liberal politics: freedom, toleration, individual rights, constitutional democracy and the rule of law. Liberals hold that political organizations are justified by the contribution they make to the interests of individuals, interests which can be understood apart from the idea of society and politics. They reject both the view that cultures, communities and states are ends in themselves, and the view that social and political organizations should aim to transform or perfect human nature. People have purposes of their own to pursue, either economic or spiritual (or both). Since those purposes do not naturally harmonize with one another, a framework of rules may be necessary so that individuals know what they can count on for their own purposes and what they must concede to the purposes of others. The challenge for political philosophy, then, is to design a social framework that provides this security and predictability, but represents at the same time a safe and reasonable compromise among the disparate demands of individuals.

1 Liberal politics

In politics, the term ’liberalism’ denotes a family of positions centred around constitutional democracy, the rule of law, political and intellectual freedom, toleration in religion, morals and lifestyle, opposition to racial and sexual discrimination, and respect for the rights of the individual.

Often these positions are associated with a suspicion of state authority, with a view that the powers of government should be constrained if not minimized, and with a confidence in the ability of individuals to organize themselves on the basis of the market, the free interplay of ideas and the loose and informal associations of civil society. Liberal support for democracy is therefore sometimes qualified by fear of ’the tyranny of the majority’ and by apprehensions about the extent and intrusiveness of the power that a populist state is capable of exercising.

These attitudes are not, however, characteristic of all forms of liberalism. In Britain, in the late nineteenth and early twentieth century, a group of thinkers known as the New Liberals made a case against *laissez-faire* and in favour of state intervention in social, economic and cultural life. The New Liberals, who included T.H. Green and L.T. Hobhouse, saw individual liberty as something to be achieved under favourable social circumstances. The poverty, squalor and ignorance in which most people lived made it impossible in their view for freedom and individuality to flourish, and the New Liberals believed that these conditions could only be ameliorated through collective action coordinated by a strong welfare-oriented interventionist state.

In the USA, since the early part of the twentieth century, the term ’liberalism’ has been associated with ‘progressive’ economic reform, a commitment to the modest redistribution of income that takes place in a welfare state, a suspicion of business and an abiding faith in the legal regulation of economic affairs. The more *laissez-faire* version of liberalism is called ’conservatism’ in the USA, and Europeans are often disconcerted to hear ’liberal’ used there as label for positions that they themselves would describe as left-wing or moderately socialist.

This is not just terminological confusion. Those in the USA who call themselves ’liberals’ do also hold the positions outlined at the beginning of this article, and their disagreement with ’conservative’ opponents is partly a live and unresolved issue about the implications of traditional liberal premises in so far as social and economic policy is concerned. Does individual freedom require private ownership? Is poverty compatible with liberty? Can civil and political rights be equal if economic power is not? Liberalism is a family of positions, and these remain important family disputes.

2 Political philosophy

In philosophy, ’liberalism’ is not just the name of a loosely organized and quarrelsome family of substantive political opinions. It refers also to a heritage of abstract thought about human nature, agency, freedom, and value, and their bearing on the functions and origins of political and legal institutions.

That heritage takes its rise in early modern English political philosophy - most notably in the work of Thomas Hobbes and John Locke §10. It is also the political philosophy of the European Enlightenment, represented in its most philosophically articulate form in the writings of Jean-Jacques Rousseau, François-Marie Arouet de Voltaire,

Henri-Benjamin Constant de Rebecque and, a little later, Immanuel Kant. In the nineteenth century, philosophical liberalism is represented, first, in the utilitarian theories of Bentham and J.S. Mill, and later in the ’Idealism’ of T.H. Green.

Inevitably, because of our proximity, it is harder to identify canonical works of twentieth-century liberalism. There was a long period in the twentieth century in which liberal philosophers seemed to lose their taste (or their nerve) for grand theory on the scale of Hobbes or Kant, a period during which they seemed to pride themselves on the piecemeal, analytic and unsystematic character of their thought. In a Cold War context, these were regarded as healthy signs of being ‘non-ideological’. That phase seems to have passed, and more confident versions of philosophical liberalism have re-emerged in the work of late-twentieth-century writers like F.A. von Hayek §3, Robert Nozick §2, Ronald Dworkin, Joseph Raz and, most importantly, John Rawls §4.

Some will quibble about one or two of the names on this list. Was Hobbes really a liberal? Was Rousseau? We should remember, however, that ‘liberalism’ has never been a label over which any group has exercised collective control. As a result, the term is at the mercy of its most casual users, and indeed the attempt to define ’liberalism’ is undertaken most commonly not by its practitioners but by its opponents, with predictable caricatural results.

Even so, the challenge is not just to correct misrepresentations. The philosophical positions that we most plausibly identify as liberal often represent distinctive expressions of ambivalence about human nature and political life, rather than dogmatic formulae in a liberal catechism. We have seen this already in the values and principles which constitute liberalism in the political sense: liberals disagree about property, economic equality and the role of the state. At the more philosophical level, liberals disagree about the nature of value, the meaning of freedom and the connection between individual and social purposes.

What follows is an attempt to lay out some of those positions and controversies. But defining liberalism is, on the whole, a frustrating pastime. There are many ways of mapping this philosophical landscape, and there is no substitute for grappling with the disparate detail of the theories propounded by particular liberal philosophers.

3 Individualism

Let us begin with some basic ethical premises. The deepest commitment of liberal political philosophy is to *individualism*, as a fundamental proposition about value. Liberal individualism has four parts to it.

First, liberals believe that the individual person is what matters for the purposes of social and political evaluation. We may be interested in the fate of a culture, a language, a community or a nation, but for a liberal such interest is always secondary or derivative. Ultimate value has to do with how things are for ordinary men and women, considered one by one: their pains and pleasures, their preferences and aspirations, their survival, development and flourishing. Of course, people do care about each other: individualism is not the same as egoism. But individualism excludes social and collective entities from the realm of ultimate goods.

There is less agreement about the grounds for this individualization of value. John Locke, writing in the seventeenth century, based it on each person being the workmanship and property of God, which meant that we were ‘made to last during His, not one anothers Pleasure’ (1690). This relation to God was direct, unmediated and unconditional in the case of each individual. It therefore established a basis for our rights with respect to one another that did not presuppose validation by larger social structures.

Modern liberalism, however, is a secular tradition, and its history since Locke’s time is largely a history of the attempt to establish this individualism without appealing to the idea of God. Utilitarian thinkers linked the notion of value analytically to desire or preference, and they inferred, from the fact that desiring and preferring were attributes of individuals, that the fundamentals of value must be individualistic too (see Utilitarianism). Those following in the tradition of Kant, on the other hand, linked value analytically to the lonely individualism of will, conscience and the sense of duty, and drew the conclusion that each person, *qua* moral agent, was entitled to be regarded as an end in themselves, not just a means to broader social ends. The Kantian view has perhaps fared better in modern political philosophy, although its underlying argument - that because moral thinking takes place at the level of individual minds and wills, individual minds and wills must also be the fundamental objects of moral concern - has yet to be rendered in a compelling form.

Second, liberals believe that there is something particularly important in the capacity of individuals to direct their actions and live their lives, each on their own terms. They believe in the importance of freedom - although what that belief amounts to is one of the controversies referred to earlier. Some define freedom in negative terms: their libertarianism amounts simply to a condemnation of force, coercion and interference in human life. Freedom, they say, is what flourishes when these constraints are taken away, and there is nothing apart from the removal of constraints that needs to be done politically in order for freedom to flourish. Positive conceptions of liberty allow the state a much greater role than this: they may see freedom or autonomy as something to be achieved, rather than taken for granted, in the life of an unrestrained individual, something that requires educated individual capacities and favourable social conditions (see Freedom and liberty).

Some conceptions of positive liberty go well beyond this, moving out of the liberal realm altogether. If freedom is identified with the performance of social duty, or attributed to individuals only by virtue of their participation in some social whole, then the resulting theory can hardly be described as liberal.

Also, if freedom is presented as the achievement of a happy few, something of which the ordinary mass of humanity is incapable, then again we are not dealing with a liberal conception. Although liberal freedom is sometimes a developmental concept, it is not an aristocratic or utopian one. The free direction of a human life is seen as something which ordinary people are capable of, under decent social and political circumstances. When Colonel Rainsborough exclaimed in the Putney Debates of 1647, ‘Really, I think that the poorest he that is in England has a life to live as the greatest he’, he gave voice to an egalitarianism that lies at the foundations of the liberal tradition (Wootton 1986: 286).

The third aspect of liberal individualism, then, is a commitment to equality. We have to be careful how we formulate this. Liberal philosophers are not necessarily egalitarians in the economic sense. But they are committed as a matter of the basic logic of their position to a principle of underlying equality of basic worth. People are entitled to equal concern for their interests in the design and operation of their society’s institutions; and they have the right to be equally respected in their desire to lead their lives on their own terms (see Equality).

Feminists have sometimes questioned whether this liberal commitment to equality extends across boundaries of gender. In the writings of Locke, Rousseau and Kant it is easy to find throwaway lines that would be described today as sexist or misogynistic. No writer in the liberal canon committed himself explicitly and at length to the emancipation of women much before J.S. Mill’s essay *The Subjection of Women* in 1868. Nevertheless, the legacy of liberal carelessness on this issue does not pose any major theoretical difficulties for the position that men and women are equal in their moral and political capacities and in the respect to be accorded those capacities. Indeed, the more challenging feminist critique is that liberals exaggerate (rather than deny) the similarities between men and women - that they fail to either acknowledge or accommodate crucial elements of ‘difference’ in moral reasoning and ethical demeanour (see Feminist political philosophy).

A fourth element of liberal individualism involves an insistence on the rights of individual reason. This involves not just freedom of thought, conscience or discussion, but a deeper demand about justification in politics: the demand that rules and institutions of social life must be justified at the tribunal of each individual’s reason.

We see here an important connection between liberal thought and the philosophical legacy of the Enlightenment. The Enlightenment was characterized by a burgeoning confidence in the human ability to make sense of the world, to grasp its regularities and fundamental principles and to manipulate its powers for the benefit of mankind. That drive to understand nature is matched in Enlightenment thought by an optimism at least as strong about the possibility of understanding society and human nature. In one aspect, this optimism is the basis of modern sociology, history and economics. But it is also the source of certain normative attitudes towards social and political justification - an impatience with tradition, mystery, awe and superstition as the basis of order, and a determination to make authority answer at the tribunal of reason and convince us that it is entitled to respect. The social world, even more than the natural world, must be thought of as a world *for us* (for *each* of us) - a world whose workings are to be understood by the active enquiries of the individual mind, not by religious dogma, mindless tradition or the hysterics of communal solidarity.

4 The economic side of human nature

Liberals accord intrinsic value to people as individuals, and attach particular importance to each individual’s

capacity to organize a life on their own terms. What terms are these likely to be? What nature of beings are these whose individual freedom we value? And what are the uses to which their freedom is likely to be put?

Critics commonly associate liberal individualism with an egoistic and acquisitive view of human nature. They say the classic liberals all gave pride of place, among human motivations, to the desire for power, pleasure and material possessions. Humanity, they argue, is reduced in liberal theory to nothing more than a competitive mass of market individuals - voracious consumers with unlimited appetites, hostile or indifferent to the well-being of others, and requiring no more of their political and legal institutions than that they secure the conditions for market activity.

The picture is not entirely a distortion. Liberal individualism does recognize that individuals' interests do not necessarily or naturally harmonize with one another. Each individual has a life of their own to lead, and there is no guarantee that one person's desires will not conflict with another's. Sometimes, as in Hobbes's theory, this is represented as an inherent hostility, a competitive diffidence and a 'mutuall will of hurting', issuing in a 'war of all against all'. Sometimes, as in John Rawls' work, it is seen simply as a postulate of mutual disinterest (rather than hostility). Mostly it is seen in Immanuel Kant's words as a matter of the 'unsociable sociability of men' - that there are things we share in common, things that drive us to society, things we can only accomplish together, as well as aspects of our nature that make us prickly, adversarial and wilfully isolated individuals.

Moreover, although - as we shall see - liberals believe that there are terms on which individuals with diverse or even opposed interests can live in peace with one another, it has never been part of their political philosophy that reason, enlightenment or socialization would put an end to this basic diversity or competitiveness. (To the extent that Rousseau suggests that the social contract might produce 'a remarkable change in man', his speculations take him outside the liberal tradition.) In the nature of things, humans will inevitably come up with diverse and opposed views of what makes life worth living, while the exigencies of our situation in the world - the moderate scarcity of material resources and our vulnerability to one another - will always furnish the raw materials for anxiety, competition and conflict (see Human nature).

A related objection is that liberals subordinate politics to economics: they see political structures merely as instruments for securing economic peace and market interaction, and they ignore the higher calling for the state outlined, for example, in the theories of Aristotle, Hegel or Hannah Arendt.

The image is accurate, but it is not clear why it should be regarded as an objection. Certainly, liberals do not regard participation in politics as an end in itself; unlike the civic humanists, they do not think that the most important virtues and activities are those oriented towards politics and the formal exercise of power over others (see Republicanism). It does not follow that they think of political participation as a narrow self-interested enterprise. In political science, the term 'liberalism' is commonly associated with interest group politics, but philosophical liberals are about equally divided on the question of whether voters in a democracy should orient their decisions to the common good or to their own interests (with the common good emerging as some sort of resultant from the political process). The point, however, is that even those who believe we should vote on our views about the common good still maintain that politics is, in the end, a means to promote the interests of individuals (*all* individuals), not an end in itself. They may believe in Rousseauian democracy, they may even hope that democratic participation can bring out the best in people (although many are dubious about that), but their firmest conviction is that individuals have interests and purposes of their own to pursue which have nothing intrinsically to do with politics or the state, and that the function of government is to facilitate those individual purposes not judge them or replace them with political or social ones.

To say that these purposes are individual is not necessarily to say that they are economic or materialistic in their content. It is surprising, in fact, how few liberal theorists have actually held the economically acquisitive picture of human nature. Hobbes did, certainly, and so did some of the eighteenth-century political economists. But many others in the liberal tradition see material motives as means to individual ends that may well be ethical, even spiritual in their content. John Locke, notorious in some circles as the apostle of possessive individualism, insisted that our primary mission in life is to ascertain what our creator requires of us in the way of conduct and worship: 'the observance of these things is the highest obligation that lies upon mankind, and…our utmost care, application and diligence, ought to be exercised in the search and performance of them because there is nothing in this world that is of any consideration in comparison with eternity' (1689 (1991): 42). Modern liberals, too, tend to stress the

ethical and cultural character of individual pursuits. We each have our own conception of happiness or the good life - a view about what makes a life worth living - and it is the diversity of individual ideals of this kind that political structures must accommodate.

In general, there is an intriguing ambivalence in the liberal tradition about whether this shift from economic to ethical individualism presents the social problem as more or less intractable. On the one hand, it seems to make the situation look better. Economic conflict is a zero-sum game: what you have I cannot have, or, worse still, what you have puts you in a better position to take what I have away from me; I therefore have an excellent reason of self-protection to deprive you of as many resources as I can. Ethical and spiritual individualism, by contrast, seems less intrinsically competitive: 'one man does not violate the right of another', wrote Locke, 'by his erroneous opinions…nor is his perdition any prejudice to another man's affairs' (1689 (1991): 42). The appropriate social posture for religious or ethical individualists seems to be the mutual indifference of Rawls' theory rather than the competition or conflict of Hobbes.

In fact, of course, that has not been our experience. Wars of religion have been at least as deadly as wars for territory or resources. We may think of commercial life as bland or shallow, but there is a certain sense of relief in Voltaire's comment about the London Stock Exchange: 'Here Jew, Mohammedan and Christian deal with each other as though they were all of the same faith, and only apply the word infidel to people who go bankrupt' (1734 (1980): 41). Even Hobbes, whose *Leviathan* is the *locus classicus* for the economic war of all against all, was adamant that the problem of the struggle for resources could be solved, since people would be willing to make concessions to a strong state that could keep the peace. But sectarian religious fervour he thought of as a form of madness, and he doubted whether the partisans of rival religious ideals could ever come to terms with one another (see Toleration).

Critics of liberalism will no doubt persevere in their charge that the tradition flatters the materialistic side of human nature at the expense of cultural and spiritual aspirations. They will say that liberals have paid too much attention to the ways in which political and legal structures can foster market economies and too little to the contribution they can make to the quality of ethical choice. A number of liberal writers have taken this criticism seriously. Joseph Raz (1986), for example, has argued that there is an aspiration towards value in the very concept of autonomy, so that a liberal commitment to freedom should not be thought of as incompatible with a social commitment to ethical perfectionism (see Perfectionism).

There comes a point, however, when liberal philosophers simply have to stand up and defend the channelling of political energies towards the real (but apparently soluble) problems of famine, plague and poverty, and away from moral, cultural and religious disputes, which promise little more in the way of progress than war, sectarianism and cults of ethical correctness. The preoccupation with economics is not based on scepticism about the ethical or spiritual dimensions of human life. It is based rather on a moderate sense of what politics can and cannot accomplish in a world where people disagree about God, value and the meaning of life, but largely converge in their desire to avoid hunger and disease and to better their material conditions.

5 The social contract

To the extent that liberal philosophy emphasizes diversity and conflict among individual purposes, it seems to steer us in the direction of anarchism. For what set of actually existing or realistically practicable institutions could possibly accommodate the individualism we have outlined?

In fact, liberal theorists have always held that something like the modern state, with its familiar institutions of law and representative government, *can* be made legitimate. They reject both the anarchist view that freedom is vindicated only in the absence of state authority and obligation and the utopian premise that a just society presupposes a radical change in human nature. This puts them in a rather ambivalent position in so far as existing 'liberal' societies are concerned - meaning here the constitutional democracies of North America, western Europe, Australasia and Japan. Liberalism has been a remarkably successful political ideology, inasmuch as its leading principles - freedom, toleration and equality before the law - have been accepted as part of the self-image or public relations of the world's most powerful and prosperous societies. Its proponents are uneasy, however, with the common inference that the social, economic and political reality of these societies is what liberal principles amount to in practice (just as Marxists were uneasy about the presentation of the Soviet Union and its satellites as

‘actually existing socialism’). They insist, quite properly, that liberalism is a set of critical principles, not an ideology or rationalization, and that it provides a basis for condemning things like deepening poverty, secretive and oligarchical government, legal abuses and the continuing legacy of racism and sexism in modern democracies. Even so, the existence of the self-styled ’liberal’ democracies is important. It helps sustain the sense that liberalism is a reformist rather than a revolutionary creed and that we already know, at least in outline, what a truly liberal society would be like. That sense of moderate reformism is not just a strategic ideological advantage. Liberalism claims to respect men and women as they are. It does not require generation after generation to undergo sacrifice for the sake of an endlessly postponed utopia. It suggests instead that political structures can be set up in now a way which represents a safe and reasonable compromise among individuals’ disparate demands.

In its classical form - in the writings of Hobbes, Locke, Rousseau, and to a lesser extent Kant - the argument from liberal premises to the legitimacy of something like the modern state was presented in terms of the social contract (see Contractarianism). The argument goes something like this.

Imagine people living outside any framework of political authority, exercising the right to direct their own lives and their own dealings with one another, in what liberal philosophers have called ‘the state of nature’. Using this as a baseline, try to model the development of political institutions as a way in which individuals exercise their freedom not as a way in which their freedom is abrogated.

The social contract model represents the functions of government in terms of a set of difficulties that such people would face in a state of nature. Conceptions of these difficulties vary. There may be an internecine struggle for resources (Hobbes and Hume); there may be an appreciation of others’ rights, but no reliable mechanism for enforcing them (Locke); or there may be disagreement about justice, with each person seeking to do what seems right or good in their opinion (Kant). The common element is that people in the state of nature would lack a reliable sense of what they could count on in social and economic life. What they most need is a secure set of rules, impartially administered and enforced, to provide a framework in which peaceful cooperation and long-term production is possible.

Government, then, is represented in terms of an agreement by each person with all of the others (in a given territory) to cooperate in the institution and maintenance of permanent rule-making and rule-enforcing agencies. The contract is not an agreement between the government and the individual. Instead, it presents legal and governmental institutions as structures of cooperation among individuals, and it uses that idea as a basis for deriving limits on governmental powers and restraints on particular individuals’ or factions’ exploitation of those powers. Tyrannical exploitation and arbitrary government are ruled out on this conception, inasmuch as they cannot be represented as any sort of improvement over the situation individuals would face if they tried to live without any political institutions at all.

Some theorists, Rousseau and Rawls for example, use the social contract idea also as a way of thinking about the content of legal rules: we can discuss what rights we have and the just distribution of resources by asking what assurances would have to be given to each individual to secure their consent to the basic structure of social arrangements. In the hands of these theorists, the social contract is a test of substantive political justification. Others see it in more procedural terms: the social contract models the construction of political and constitutional mechanisms, which will then work out substantive solutions on a basis that is relatively independent of the contract idea. Hobbes’s theory is the most extreme example of this: the Hobbesian contract is simply an agreement to authorize an individual or organization (a ’sovereign’) to solve the problems that generate conflict in the state of nature in any way that promises improvement. The absolute authority with which the sovereign is thus endowed has led some to deny that Hobbes is a liberal. Certainly, he is not wedded to the positions identified with liberalism at the beginning of this article. But his underlying political philosophy is liberal: his value premises are individualistic, and he is unyielding in his view that political institutions (with the powers he accords them) must be justified in relation to the interests of each individual, as well as in his optimism that such justification is possible.

Not all liberal philosophers appeal to the idea of the social contract. Many prefer to develop their theories without the mediation of this model. The arguments of J.S. Mill’s 1859 essay *On Liberty*, for example - which many regard as the quintessential statement of liberal principles - are presented directly as claims that individuals are entitled to make, against their society and their government, without any historical pretence that governments were set up by

individuals to validate those claims (see Law, limits of). Others use the social contract to justify some but not all of the political constraints they propose. In the theories of John Locke and Robert Nozick, the social contract argument presupposes a distribution of 'natural' property rights. For them, the function of the social contract is to support and police these rights, not reconceive or redistribute them. In other words, Locke and Nozick propose that property rights should be justified directly in moral argument, without appealing to the social contract idea. I suspect that something like this is true of all liberal theories. The social contract is an intermediate rather than a fundamental idea: one that presupposes that individuals are free, equal and rational, and that political power requires a justification which connects with the interests of each of them.

When it is understood in this way, as a method of modelling the force of certain deeper assumptions or theorems about justification, the social contract can be used as a purely hypothetical device in normative argument. As Kant and Rawls have pointed out, we need not be embarrassed by the fact that no such contract ever took place. It is still a useful test to apply to a constitution or to a set of laws. For if we conclude, even hypothetically, that our laws or our constitution would not have commanded the agreement of all those who are constrained by them, we will have discovered a significant dissonance between our political arrangements and the fundamental (pre-contract) notion of respect for each individual - a dissonance that ought to be of concern to liberal philosophers whether they are interested in the niceties of contract theory or not.

Liberalism, Russian

Unlike early English liberalism which stressed individual freedom from state control and from the 'tyranny of the majority', Russian liberalism generally emphasized the importance of legality in government, the state's positive role as guarantor of civil liberty, and the gradual achievement of social justice through reform. In the century between Peter the Great's death in 1725 and the Decembrist uprising of 1825 various politicians and thinkers proposed the introduction of representative institutions into the Russian government and recommended that serfdom be abolished in the Empire. These proposals reflected admiration for Western European models of government and the impact of the Enlightenment on Russia's ruling elite. Because the autocracy ultimately rejected these proposals and made public discussion of them all but impossible, liberalism did not take root in this period. The genesis of Russian liberalism as a philosophically elaborated, politically coherent movement occurred after the death of Tsar Nicholas I in 1855, when the government eased censorship and announced its commitment to peasant emancipation. Mid-nineteenth-century Russian liberalism owed its intellectual inspiration to Hegelianism and French juste-milieu *liberalism. Russian liberals argued that social progress in the empire had almost always come about at the state's initiative; they could scarcely imagine building a just society without the cooperation of a strong state.*

At the beginning of the twentieth century Russian liberals confronted what proved to be an insuperable challenge: how to establish a viable constitutional order in an empire riven by social and ethnic strife where neither government nor the powerful socialist movement favoured a rule-of-law state. Wrestling with this difficulty, the liberals split into two factions: a 'left' or 'radical' wing that valued social justice over the sanctity of property rights; and a 'right' or 'conservative' wing that valued legal equality over social equality, and therefore interpreted socialism as a species of utopianism. Between 1905 and 1917 the liberal movement reached its political zenith, as liberal politicians exercised their influence in the State Duma and opposition movement. Following the October 1917 Bolshevik Revolution liberalism was banned in the Soviet Union. It re-emerged, albeit in altered form, during communism's collapse when neo-liberals claimed for liberalism a prominent position in the 'normal' constellation of Russian political forces. The main goals of post-Soviet liberalism are the defence of civil and political rights, the establishment of the rule of law, the assertion of individual property rights and the gradual construction of a market economy.

1 Absolutism, Enlightenment and proto-liberalism

The post-Petrine Russian government was a unitary absolutist state that, in theory, allowed neither individual nor corporate autonomy. Until the mid-nineteenth century the state depended on a tacit alliance between the Crown and the landed nobility dedicated to the continuation of serfdom. Between 1725 and the Decembrist uprising in 1825, however, various politicians and thinkers - among them Count Dmitrii Golitsyn (1663-1738), Count Nikita Panin (1718-83), Denis Fonvizin (1744-92), Nikita Murav'ëv (1796-1843), Mikhail Speranskii (1722-1839) and Nikolai Novosil'tsov (1761-1836) - proposed to establish new agencies to limit the Tsar's personal authority or to subject the Crown to the higher authority of a fundamental law; in certain instances, these proposals were accompanied by recommendations that serfdom be abolished. Historians have sometimes interpreted these reformist efforts as the origins of Russian liberalism.

However, only two eighteenth-century Russian thinkers elaborated philosophical justifications for liberal government, Semën Desnitskii and Aleksandr Radishchev. Desnitskii (?-1789), a professor of law at Moscow University, was influenced by the Scottish Enlightenment, particularly by Adam Smith whose lectures he heard at Glasgow and whose *Theory of Moral Sentiments* he often quoted. Desnitskii divided social evolution into four ascending stages - hunting, pastoral, agricultural and commercial society - each having a legal system peculiar to it. He thought that representative government was appropriate to commercial society; popular elections expressed the electorate's historically conditioned deference towards the wealthy; and that the duty of the wealthy was to serve the less fortunate, as the dictates of virtue require. Desnitskii criticized Russian absolutism as lawless and arbitrary. He proposed that the imperial government establish an elective Senate, with representatives from the commercial classes as well as the nobility, to advise the crown on legislation. He was one of the first Russian advocates of civil rights for women.

Radishchev (1749-1802) has usually been classified as a revolutionary because he rejected nobiliary privileges, noted that tyrannicide has sometimes been the penalty for despotism and predicted a peasant revolution. However, he was far from consistent and, with equal justice, may be considered a forerunner of liberalism. Radishchev's principal commitment was to equality before the law. He followed Mably in asserting that good government requires every citizen, including the sovereign, to submit to the law; like Mably and Rousseau, he thought that government should depend upon citizens' mutual consent without which the social compact dissolves. He admired the English and American systems for their devotion to legality and encouragement of an active citizenry. His famous tract, *A Journey from St Petersburg to Moscow* (1790), can be read as an explicit warning to the Russian government and nobility to mend their ways, lest the peasants rise in bloody revolt. Although he was a republican, Radishchev did not support the Jacobin terror, because the terrorists violated civil rights. Unfortunately for Russia, Desnitskii's work was quickly forgotten and Radishchev's tract was burned by the imperial authorities (see Enlightenment, Russian).

2 Mid-nineteenth century liberalism

Russian liberalism's crystallization in the 1850s owed much to external circumstances, especially the Crimean debacle, the death of Tsar Nicholas I and the accession to the throne in 1855 of the reform-minded Alexander II. However, these events only punctuated the evolutionary process in which a portion of educated society committed itself to liberal values. During the 1840s, at the height of the Westernizer-Slavophile debate over Russian national identity, the Westernizers defined Russia as a member of the European family of nations. The historian Timofei Granovskii (1813-55) claimed that, under the aegis of the modern state, European societies had been gradually advancing towards political liberty. He hinted that even in Russia this movement would culminate with a *Rechtsstaat* wherein all individuals would have the possibility to develop their potential freely. In 1847 the jurist Konstantin Kavelin (1818-85) published a Westernizer manifesto, 'A Brief Survey of Juridical Relations in Ancient Russia', asserting that Peter I's reforms represented a victory for the principle of free individuality. Kavelin hoped that the contemporary Russian state and educated society would build upon this victory by inaugurating broad new reforms. In St Petersburg during the late 1840s and early 1850s he studied the peasant question in collaboration with other junior officials interested in serfdom's abolition; his 1855 'Memorandum on the Emancipation of Peasants in Russia' was probably the most compelling justification for ending serfdom written by a Russian intellectual. By the early 1840s, Granovskii, Kavelin, the literary critics Pavel Annenkov (1813-77) and Aleksandr Druzhinin (1824-64), the historian Sergei Solov'ëv (1820-79) and the oft-derided 'philosophical tea-merchant' Vasilii Botkin (1811-69) had arrived at a consensus on the values they thought essential to free society: respect for law, individual dignity, freedom of conscience, toleration of intellectual diversity and hostility towards serfdom. All agreed that, under Russian conditions, the state would have to assume primary responsibility for realizing these values in practice. The Westernizers' worldview was underpinned by Hegelianism, a current that dominated Russian thought during the second quarter of the century (see Hegelianism, Russian). Hegel's evolutionary conception of history, his efforts to reconcile the thinking individual's autonomy with the collective life of the *polis*, his antipathy to unmediated state power and his support for constitutional monarchy implicitly informed the Westernizers' approach to Russia's problems.

The credit for transforming the amorphous Westernism of the 1840s into a recognizable liberal programme belonged to Boris Chicherin (1828-1904), arguably the leading Russian liberal theoretician of the century. He thought that liberals should concentrate on achieving seven objectives: freedom of conscience; peasant emancipation; freedom of speech; freedom of the press; academic freedom; publicity of all government activities; and public legal proceedings. In his classic *On Popular Representation* (1866), he sharply distinguished between the civil rights mentioned above and political rights such as voting and representation in a national assembly. He criticized Western liberals such as John Stuart Mill for mistakenly identifying liberalism with the achievement of political rights. He maintained that Russians should accustom themselves to civil rights and the legal culture entailed by such rights before establishing a constitutional government. His faith in monarchy as an engine of legal reform, his hesitations about the advisability of constitutional government in Russia, his bitter opposition to socialism, and his allegedly doctrinaire Hegelianism led many contemporaries to consider him a conservative or even a reactionary. He advertised himself as a 'conservative-liberal', professing faith in the platform 'strong government and liberal measures'. Nevertheless, late in his life Chicherin laid greater stress on individual freedom and the need for a constitution. His last major work, *Philosophy of Law* (1900), was a sweeping defence of

individual freedom in the spirit of what Friedrich von Hayek later called ‘classical liberalism’. Chicherin’s individualism profoundly affected the philosophers Nikolai Berdiaev (1874-1948), Pavel Novgorodtsev (1866-1924) and Pëtr Struve (1870-1944) who came to share his aversion to socialism and collectivism.

Westernism was also the main source of Aleksandr Herzen’s ‘Russian socialism’, a doctrine that contributed to the birth of Russian populism and anarchism but that has sometimes been seen as affiliated with the liberal tradition. Herzen (1812-70) was a lifelong believer in individual freedom, an opponent of tyrannous abstractions and an occasional advocate of republican government. His greatest champion, Sir Isaiah Berlin, regards him as a harbinger of contemporary liberal pluralism; others have associated him with libertarianism and the Russian federalist movement. However, Herzen was famously dismissive of European *juste-milieu* liberalism. He hated the modern bureaucratic state, wished for the triumph of a ‘social republic’ based on the peasant commune and anticipated a new socialist age in history. His revolutionary and millenarian side had little or nothing in common with the statist liberalism of Chicherin (see Herzen §3).

3 Late imperial liberalism

Between 1890 and 1917 Russian liberals redefined their political agenda. They pressed the government for a constitution and national elections, a concession reluctantly granted by Nicholas II in October 1905. In the State Duma from 1906 to 1917 liberal parties played a signal role, but they overcame neither the Tsar’s scepticism about representative government nor socialist opposition to the legal order. During this turbulent period liberal thinkers were divided over which objective deserved priority - legality or social justice. Left-wing liberals sought the rule of law as well as social justice but generally valued the latter over the former. Their practical aims - land redistribution from the nobility to the peasantry, an eight-hour day for workers, and a social-insurance state - overlapped with the moderate socialist agenda so extensively that left liberals tended to think of socialists as their natural allies. Indeed, Pavel Miliukov (1859-1943), Russia’s best-known liberal politician, boasted in 1905 that ‘our programme is undoubtedly the most leftist of all those advanced by similar political groups in Western Europe’. The philosophical foundations of left liberalism derived from disparate religious and secular sources. The religious philosopher Vladimir Solov’ëv (1853-1900) combined social Christianity with a Kantian insistence on individual dignity and the objectivity of ethics when he argued that a good society must guarantee to each member that minimum of welfare necessary for a dignified existence. Although Solov’ëv himself cannot be counted a left liberal, his ideas developed a wide currency in the younger generation which sought in Christian egalitarianism a solution to Russia’s social problems. The Ukrainian liberal Bogdan Kistiakovskii (1868-1920), influenced by the Austrian *Kathedersozialist* Anton Menger, discovered a historical continuity between liberalism and socialism: he predicted that civil rights and the liberal *Rechtsstaat* would prepare the way for social rights and a socialist rule-of-law state. After the 1917 revolutions, the liberal-socialist synthesis reached its culmination with Sergius Hessen (1887-1950) who predicted a new type of liberal state - one that would foster conditions in which citizens might choose the good without being hindered by economic privation.

The ‘right’ or ‘conservative’ liberals followed Chicherin in stressing that cultivation of individual freedoms and respect for law must take priority over redistributing wealth and the social insurance state. In 1909 authors of the *Vekhi (Signposts)* symposium accused Russian radicals, including left liberals, of supporting social equality at the expense of legality and individual freedom (see Signposts movement). The historian Mikhail Gershenzon (1869-1925), an outspoken defender of individualism, described egoism as the ‘great force’ that had made of the Western bourgeoisie ‘God’s unconscious instrument on earth’. Struve’s essay in *Signposts* attacked the radicals’ proclivity to ‘stand aside’ from the government rather than cooperate with it, to preach revolutionary destruction rather than to seek self-perfection as true lovers of liberty ought to do. Connecting all the *Signposts* essays was the assumption that the inner, especially religious life of the individual ‘is the only sound foundation for any social structure’. A devastating critique of socialism from a conservative liberal perspective came from Novgorodtsev, whose *On the Social Ideal* (1911-16) interpreted Marxism as a doomed millenarian religious movement aimed at achieving the Kingdom of God on earth; Novgorodtsev juxtaposed to Marxism belief in a transcendent God, in natural law, in a *Rechtsstaat* and in individual dignity. During the political crises of 1917-18 several conservative liberals, among them Struve and Novgorodtsev, supported a temporary military dictatorship as an alternative to socialism. This policy showed the degree to which right liberals feared socialism and ‘revolutionary democracy’, as well as the unpalatable choices that confronted all Russian liberals at the end of the old regime.

Of course, the lines between left and right liberals were far from absolute. Struve moved from left to right between 1902 and 1909, whereas Miliukov tried to bridge the distance between the two wings of the party. Some thinkers - Novgorodtsev is a good example - at times straddled the left-right philosophical divide. In any event, the two groups shared a central conviction, - namely that a strong government is a necessary precondition of liberty, however defined. Thus, in the main Russian liberalism was state-centred rather than federalist, pluralist or libertarian.

4 The revival of liberalism in post-Soviet Russia

Soon after the Bolshevik Revolution, the Soviet government banned liberal political parties. From 1917 to 1991 the Soviets treated liberalism as an ideological deviation punishable by public obloquy, arrest, hard labour or even death. Public advocacy of liberal values was therefore out of the question; sadly, the academic study of liberalism's legacy was circumscribed. Even before 1991, however, dissident intellectuals supported certain elements of the liberal worldview, especially guarantees of civil rights and government legality. During the 1970s, the most remarkable of these thinkers, the physicist Andrei Sakharov (1921-90), sought to combine socialist welfare with civil and political rights of the 'Western' type. Between the mid-1970s and early 1980s he jettisoned his support for Soviet power; before his death in 1990 he was preparing a draft constitution the central tenets of which were guarantees of human rights and the division of government authority. Philosophically, Sakharov was a *naïf*, but he succeeded in endowing his humane vision with the force of common sense. After the collapse of the USSR in 1991, self-described liberals devoted themselves to two short-term objectives: destroying the Communist Party's hold over society and demolishing the command economy. Their long-term goals were the defence of civil and political rights, the gradual construction of a market economy, and creation of a rule-of-law state. Apparently, none of these goals was perceived as inherently incompatible with revitalization of a powerful centralized Russian state. Thus, while many liberals enthusiastically supported ending the Soviet empire and permitting devolution of certain prerogatives to local or regional levels of government, they also wanted a powerful Russian presidency in Moscow. Whether post-Soviet liberalism can contribute to the diminution of economic and political strains generated by the disappearance of the communist system, whether it can bridge the gulf between a strong state and individual liberty, and whether it can manage to balance property rights with social equality remains to be seen. At the close of the twentieth century, liberalism no longer exists as it did for so long in Russia's past, clandestinely, 'behind seven seals, beneath seven locks', as an untried, mysterious and therefore badly understood alternative to absolutist government.

Liberation philosophy

Philosophy of liberation emerged in Argentina early in the 1970s with the explicit intention of proposing a liberating alternative to the diagnosis of structural dependence offered by the social sciences (particularly the so-called 'theory of dependence'). Some of the original intentions of liberation philosophy were to make poor and marginalized people the subjects, or authors, of philosophy and to collaborate in the process of distancing philosophy from academia and exclusively professional settings. Social conflict and pressing national needs were topics of debate at that time. All thought started with the recognition and assessment of the experience of alterity. Horacio Cerutti-Guldberg has proposed the phrase 'philosophies for liberation' as this kind of reflection deals with multiple philosophical positions and privileges the historical process over philosophy.

1 Initial postulations

In 1973 some theses were formulated outlining the goals of an incipient philosophical programme shared by some Argentine philosophers who were the driving force behind liberation philosophy. One goal was to create a universally valid, although historically situated Latin American philosophy. The intention was also to confront the situation of structural dependency legitimized through a self-serving and academicist philosophy as well as to explain philosophically the needs of the great exploited majority and the urgencies of the poor and oppressed Latin American people. These poor people would appear as the bearers of a historical innovation to be theorized through liberation philosophy.

Shortly after this programme was enunciated, it was divided into at least four discursive variants. These products of diverse theoretical foci and political and ideological positions had an impact on the philosophy. One could no longer justifiably speak of a single liberation philosophy as a movement or common programme. These variants presented in a very coherent way their theses regarding their point of departure, subject, methodology and conception of philosophy.

2 Four discursive variants

Ontologicist philosophy postulated as its point of departure a historical zero, as if one could begin with a *tabula rasa* - the mind in its uninformed state - regarding world philosophical tradition. The task of elaborating a new nondialectical rationality was undertaken. The task was to establish the most characteristic way of being in the world for the Latin American. The contrast between the Spanish verbs, *ser*, meaning the permanent state of *being*, as in 'I am Bill, or Jane' and *estar*, the changing state of *being*, as in 'I am happy, or sad' was emphasized as the key to understanding reality. It was the 'people' who were spoken about within the area of ontologicist philosophy as opposed to the 'liberal individual' or the 'proletarian class'. The philosopher would translate everyday events into philosophical language. In the face of Western rationalism, this variant contrarily valued and recognized the irrational dimensions of life. Gunther Rodolfo Kusch and Mario Casalla are representatives of this position.

Analectic philosophy was rooted in a criticism of Eurocentric or North Atlantic modernity. It rejected Latin American historical memory as purely imitative and therefore justifying its own domination. The imploring face of the poor would be the point of departure which would bring about analectic behaviour capable of opening up to all that is new and beyond the dialectic totalities. The philosopher would be a prophetic teacher capable of giving form to the message of those without a voice. The otherness and exteriority of the marginalized would be secured by divinity, the absolute Other. Subscribers to this viewpoint include Juan Carlos Scannone and Enrique Dussel.

Historicism warned that the origins of a philosophy which began with the experience of alterity should recognize its foundations in Latin American history. A historiographic reconstruction of Latin American philosophical memory constitutes a valuable aid in this effort. Contrary to the Hegelian model, which reduces political freedom to freedom of thought, historicism proposed concentrating on those subjects who reformulate popular demands and the way in which they reform them starting with their own interests. It defined itself as a comprehensive philosophy of the marginal and a new way of thinking which anticipated the future. Arturo Roig has applied himself to the theory of historicism.

Problematization of philosophy was the reconceptualization of philosophy, questioning the unfounded claims of originality and the attempt to begin from a historical zero. This version favoured the liberation process over

philosophy and reclaimed the express mediation of the social sciences and ideological self-criticism. It strove for the deprofessionalization of philosophy and articulated the historical dimension in conjunction with the systematic. Practitioners of this theory are Manuel Ignacio Santos, Severino Croatto and Horacio Cerutti-Guldberg.

3 Exterior and interior exile

In under three years, many people were working on the philosophy of liberation in each of its four variants. After the Argentinian military coup in 1976, a good portion of the philosophers who were adherents to the last three previously mentioned variants had already been removed from their teaching posts in the national universities. This was owing to various types of sophistry which led to expulsion or to contracts not being renewed. Some academics had already left the country; others had to abandon academic activity in order to survive, else they altered the scope of academic production. Practitioners of ontologicist philosophy yielded to the new repressive politics imposed by the dictatorship and there was no shortage of people who softened their positions or made them more flexible in order to coexist with the new regime.

Those who left the country, particularly Roig, Dussel and Cerutti-Guldberg, continued to advance and revise their positions, bringing about a wide and generalized debate which streamlined many theses, redefined foci and enriched initial arguments. Nevertheless, it seemed as though the basic positions were maintained to the point that works which can be situated in any of the four modalities mentioned have continued to be written.

4 Latin Americanization and globalization of the debate

The tireless work of those in exile promoted debate on the diverse modalities of this philosophy throughout the Latin American region and continued adding contingents of philosophers of diverse nationalities to the production of a body of thought which acquired regional nuances. In different parts of the world, especially in the USA and Europe, the debate on these issues was prolonged. The following points have been discussed extensively: the cognitive scope of the notion of the people as a collective of exploited social sectors united against all forms of dependency, attitudes towards historical and philosophical memory, the role of the philosopher as theorist or preacher, the ideological dimension of argumentation, the political consequences of the philosophical consideration of alterity, the insufficiencies of philosophy in the face of feminist or indigenous demands, conceptual ambiguities, interpretative difficulties of the same discursive modalities, the vague boundaries of the phenomenon of liberation and the relationships between the social sciences and philosophy.

The convergence of Latin American philosophy and liberation philosophy strengthened both traditions but also led to much confusion. An example of one type of confusion was the idea that Latin American philosophy has always been a liberation philosophy. From a historiographic viewpoint, this gives the term an excessive range.

5 Work in progress

After more than two decades of development of liberation philosophy, the branches of current research can be characterized as follows: ontologicism remains stable and does not have many variants, although studies of Kusch’s work are under way which would incorporate revised arguments. The progress of analectic philosophy is a little more convoluted. On the one hand, it bears a resemblance to ontologicist culturalism, while on the other hand, it is influenced by Marx whose work reveals antecedents and confirmations of the analectic version of liberation philosophy. An international and intercultural debate has arisen and has been advanced between analectic ethics of liberation and the ethics of German moral philosopher, Apel. From historicist and problematizing positions, works on the history of ideas in Latin America have increased and their methodological and epistemological connotations have been under debate. Several research projects are under way. The debate over the idea of utopia and its heuristic power has intensified and an improved theoretical formulation of the utopian is being researched. Concern grows for the rethinking of democracy, the state and connected phenomena, and an interesting debate between the theses of the philosophies of liberation, modernity and postmodernism has been outlined. After the assassination in 1989 of Jesuit Ignacio Ellacuría, a leading liberation scholar, and his companions in El Salvador, research has burgeoned to continue his effort to establish a tradition of Latin American liberation philosophy after Xavier Zuribi.

6 Perspectives

In its primary international arenas, philosophy of liberation has been identified sometimes exclusively with analectic philosophy. In reality, 'liberation philosophy' has gone beyond analectic philosophy, which is a long way from exhausting the concerns and emergent theories of the 1970s. The confusion between liberation philosophies and other variants of Latin American philosophy has not helped. A careful and nuanced division of positions and arguments should make feasible a qualitative advance in reflection.

Trapped in its formulations with an ambiguous or salvationist language without sufficient capacity to settle internal struggles, it is barely worthwhile advancing the idea of a homogeneous and unified philosophy of liberation. It would seem more fruitful to advance the progress of and research in the promotion of dialogue based on the following facts relating to Latin American and global reality: the fruitfulness of opening up to conceptual consequences of the experience of alterity, the growing increase in poverty as an almost uncontrollable phenomenon of the world economy, the intolerable injustice of the social structures of the world in the late twentieth century, the scientific and technological revolutions that modify the very guidelines of the political agenda and the demands for participation and the dissatisfaction of the masses. Many of the questions formulated through the philosophies for liberation directly address serious economic, social, cultural, religious, ethnic and political problems of the world in the late 1990s. The challenge consists of building better conceptual weapons to confront these problems theoretically and practically.

Liberation theology

Also known as theology of liberation, liberation theology is simultaneously a social movement within the Christian Church and a school of thought, both of which react against human suffering due to poverty and various forms of oppression. The essence of liberation theology consists in an interpretation of Christian salvation that retains its transcendent eschatological content and draws out its historical dimensions and their implications for personal life, the social sphere and the public action of the Church. Salvation contains various levels of liberation.

Liberation theology is most commonly associated with Latin America, where it emerged during the 1960s. As both movement and theology, it is at present a worldwide phenomenon, taking on different characteristics according to culture, situation, the kind of oppression that predominates, and concrete political and social exigencies. Although some liberation theologians have employed Marxist language as a tool for social analysis, the underpinnings of liberation theology lie in Christian faith.

Liberation theology is predominately Roman Catholic in Latin America because of the Catholic majority; but as a movement and a school of thought it unites Catholic and mainstream Protestant Churches. Evangelical Christians are often antipathetic to liberation theology because of their individualism and other-worldliness.

1 Historical development

The conditions against which liberation theology is a reaction have their prehistory in colonialism and neo-colonialism. Liberation theologians and historians chart the history of colonialism and analyse the social, economic and political dependencies of developing countries upon developed nations. In varying degrees, the relation of Latin American nations to the developed nations is mirrored in each developing country by a two-class system of educated, resourceful people and the poor or destitute majority.

The most immediate explanation of liberation theology, however, lies in the actual conditions in which poor people live and the natural human reaction to them. Christian theologians, among others, came to recognize the massive poverty of the majority of people in Latin America as radically unjust and systemically supported by social institutions. As various organizations of students and workers mobilized for social justice, the moral perception of the deadly character of destitution became a condition for appreciating the liberating potential of theology. Theologians began to interpret Christian faith as responsive to the cause of justice and the poor. By the early 1960s, essays in what would come to be called liberation theology were already being written.

Two public events in the life of the Roman Catholic Church in the 1960s served as a catalyst for liberation theology. One was the Second Vatican Council (1962-5). Its *Pastoral Constitution on the Church in the Modern World* (*Gaudium et Spes*) described the Church as deeply concerned with human life in history and with the problems of poor peoples. It encouraged regional churches to internalize this message and adapt it to each local situation. The other was the Second General Conference of Latin American Bishops in 1968, in Medellín, Colombia, which produced documents describing the social situation of the poor majority, characterizing it as institutionalized violence and sin. The bishops promised that the Church would address these inhuman conditions. The corporate commitment of the hierarchy of the Latin American Church encouraged the movement of liberation theology on all levels.

The 1970s witnessed an outpouring of work in liberation theology, Gustavo Gutiérrez's *A Theology of Liberation* (1971) being the 'classic text'. The themes that dominated the discussion during this decade were the distinctive method of this theology, by contrast with theology in Europe, and the fundamental nature and role of the Church in society. This period ended with the Third General Conference of Latin American Bishops at Puebla, Mexico, in early 1979. Marked by heavy internal Church politics and closely watched by people outside Latin America, its documents roundly supported liberation theology while balancing it with more traditional themes.

The next period of development, through the 1980s to 1992, included developments in theology, Christian life, and ethics, as well as an effort by the Vatican to control liberation theology. Two documents were issued in 1984 and 1986, the first condemning specific extremes perceived within liberation theology, the other developing the Vatican's version of the anthropological grounds of social liberation and emancipation. Leonardo Boff, a Brazilian liberation theologian, was forbidden to lecture for one year in 1985. By the time of the fourth meeting of Latin

American bishops, in Santo Domingo in 1992, which also commemorated the five-hundredth anniversary of the coming of Christianity to the Americas, the Vatican had quieted episcopal support for liberation theology.

The development of liberation theology extended well beyond Latin America. After Medellín, other parts of the developing world immediately resonated with a theological method and language which addressed their own problems of poverty and social marginalization. But in each case, liberationist themes were received into a different situation with a distinctive modality. In south Asia, liberation theology combined with the need for interreligious dialogue and cooperation; in Africa, liberation theology merged with movements of inculturation. Liberation theology is recognizably pluralistic; common formal themes take different concrete shapes around the world.

The Vatican is not hostile to the essence of liberation theology; Vatican teaching is strongly influenced by it. At the Synod of Bishops meeting in Rome (1971), in Paul VI’s influential encyclical *On Evangelization in the Modern World* (1976), in the Vatican’s *Instruction on Christian Freedom and Liberation* (1986), in John Paul II’s encyclical *On Social Concern* (1988), the leadership of the Roman Catholic Church has endorsed the centrality of the commitment to the welfare of the poor and marginalized which is the core of liberation theology. The agenda and language of liberation theology has thus become part of Catholic theology and social teaching from the centre, so that the internalization of liberation theology has spread not only laterally but also back through the centre to the whole Church.

Liberation theology extends beyond the confines of Roman Catholicism and Latin America, and cuts across the confessional lines of the mainstream Churches; it is ecumenical. Also, the social captivity and oppression to which it responds transcend sheer poverty. The negative reality underlying the Black liberation theology in South Africa and the United States is racism. Black liberation theology in the USA developed autonomously out of the remnants of slavery in US society, the civil rights movement, and the language and spirituality of the Black Churches. This liberation theology became articulate in the 1960s through the impetus of Martin Luther King, Jr, and, more formally, the writings of James Cone, its leading theologian. Pervasive androcentrism and patriarchalism are addressed by feminist liberation theologians such as Rosemary Radford Ruether, and this theology too has its own prehistory (see Feminist theology).

Although the term ‘liberation theology’ refers to current movements and modes of thought, these have a tradition that extends back through the whole history of the Christian Church and finds deep roots in the Jewish and Christian Scriptures. For example, the language of liberation theology is closely analogous to the discourse of the prophets and Jesus’ own concern for those marginalized in his society. The term ‘liberation’ is thus a present-day symbol for something essential to the Christian message. A form of liberation theology appears wherever there is systematic destruction of human freedom.

2 Liberation theology as a movement

Liberation theology is generated by a social movement broader than the Church but also reflected in the Church. In Latin America, this was a people’s movement based on an insight into the sheer negativity of structural poverty and injustice and a committed effort to change society. By definition, the movement that liberation theology represents is located on the left of the political spectrum. Its constituencies are rural peasants, urban squatters, the unemployed, and exploited workers. Its allies are often students, middle-class and educated people open to change, and various organizations dedicated to social amelioration. What is true in Latin America finds its analogies in other places.

Various mechanisms structure and sustain the movement. The principle-turned-slogan that supports the liberationist agenda from within the Church at large is ‘the preferential option for the poor’. This principle developed in the wake of Medellín and was formally accepted at Puebla in 1979 and endorsed by Vatican documents and papal statements. The principle is not meant to be divisive but to affirm that the whole Church in all of its members should reflect the love of God that reaches out especially to those who suffer most and are marginalized. In fact, however, the principle divides because it reflects actual social divisions. In most places where liberation theology has taken hold, clear ideological differences distinguish the Churches of the wealthy and those of the poor. The parish whose constituency is the poor is the main locus of the liberation movement. This is where poor people come together, where Christian ministry is mobilized, where various organizations address

specific needs, and where Christian liberation language is heard in worship and public devotion.

In some respects even more fundamental are ‘basic ecclesial communities’. These are small groups of Christians, usually homogeneous so that everyone knows each other, which meet regularly for prayer and reflection. They developed simultaneously with the liberationist movement in Brazil in the 1960s and now exist worldwide. Many combine faith and the practical concerns of survival in daily life. These communities are subgroups within a parish and, when faced with clear social objectives, are animated with a liberationist spirit.

The liberationist movement is sustained by organizations that draw people together from across the lines of basic ecclesial communities, parishes and dioceses. Regional and national agencies address issues of justice. Workshops, conferences, institutes and summer schools focus reflection on liberation theology and animate the growth and social coherence of the movement. Different organizations address specific objectives.

Finally, at the core of the liberationist movement is a distinctive piety and manner of living the Christian life. This spirituality includes responsible and committed service to the poor. In its ideal form it thrives on the idea of the human solidarity of all. It acknowledges God present within the poor, animating them to take control of their lives in the face of oppression.

3 Characteristics and significance

The theology of liberation as a form of thought and a body of literature grew up out of the movement. Some representative theological leaders are: the late Juan Luis Segundo, a Jesuit from Uruguay who studied in Paris and began writing in the early 1960s; Gustavo Gutiérrez, a diocesan priest from Lima, Peru, who studied in Louvain, Lyons and Rome, and began writing in the late 1960s; José Míguez Bonino, a Methodist theologian from Argentina who after studying in the USA undertook seminary teaching in his home country; Leonardo Boff, a Brazilian and former Franciscan who completed his doctorate in Germany in the early 1970s and began teaching in a seminary in Petropolis; and Jon Sobrino, a Spanish-born Jesuit teaching in San Salvador who also studied in Germany and began writing in the mid-1970s. This first generation of liberation theologians, still active in the 1990s, is joined by a new generation of theologians who grew up as liberationists.

Five typical characteristics of liberation theology seen in connection with some of the major topics of Christian theology define its distinctiveness; these are described below.

First, broadly conceived, liberation theology’s method is hermeneutical: it interprets the past symbols of Christian scripture and history on the basis of the questions raised by the world of the suffering poor. The general goal is to make sense of the Christian message for the innocent victim of human oppression. Theological questions thus arise out of the actual situation of the people for whom liberation theology offers a voice. The option for the poor is a premise of the theology and links it with the movement of liberation praxis. Social sciences are employed to gain a critical appreciation of the situation. Some Marxist analysis is used by some liberation theologians as a tool to understand society and history, but without the philosophical premises of Marxist doctrine. The goal of the theology is a historically critical understanding of the Christian message that will engender further emancipatory praxis.

Second, liberation theology is historically conscious in dealing with Jesus Christ. Its Christological reflection begins with the human life of Jesus and not with doctrines about him. Jesus’ historical mission, particularly his prophetic judgments, displayed concern for people who either suffered physically or were excluded by social censure. Liberation theologians find humanization, compassion, healing, and empowerment of freedom dramatized by Jesus. Understanding the doctrines about Jesus begins with his ministry. That Jesus was raised from death, that Jesus is divine - these classic doctrines mean that at its deepest level salvation is liberation by God from sin and final death. But they also give divine sanction to Jesus’ historical ministry as representing the will and values of God for human life. Jesus embodies God’s salvation in the end and God’s salvific will and power within history.

Third, liberation theology proposes a doctrine of the Church that engages society. Following the lead given by Vatican II’s decree on the Church in the modern world, liberation theology regards the Church as an agent of God’s intentions for human life in history. It continues the mission represented in Jesus’ ministry. The Church is to be a sign of God’s love liberating people. Membership of the Church does not imply passivity, but a dependence on God that generates creative action on behalf of the poor. Sacraments are interpreted as vehicles for nurturing

and empowering the Christian life of service. Publicly, the Church cannot avoid being involved in social issues, as distinct from party politics, and should always be concerned for society's weakest members. The role of the Church in society is to preserve a tradition of humane Christian values as a critical context for public policy.

Fourth, liberation theology promotes a this-worldly religious life. Christian faith itself is closely connected with praxis, with a reflective, committed way of living. Christian life consists in an imitation of Christ according to the demands of society. It consists in being a member of a mission Church, which entails some active assumption of responsibility for that mission. Liberation spirituality combines contemplation and action, mysticism and politics. It relies on a notion of God's grace that does not stymie but empowers human freedom in history.

Fifth, liberation theology is intrinsically ethical. Liberation theologians have criticized the absolute right of private property, various forms of capitalism, and the national security state. The option for the poor, a bias towards socialism, and the involvement of the Church in political and social issues raise ethical questions. How can a theology that is partisan for one group be ethical? What kind of ethical discernment is needed for a Christian praxis in this or that situation? Are there general norms for an ethics of Christian liberation? These questions were addressed from the very beginning in liberation theology, but in a variety of different ways and usually within the context of broader theological analysis. Gradually a more systematically focused liberation ethics appeared, one which examines the foundations of Christian liberation ethics and its principles and norms.

Liberation theology consists in different theologies that share a number of basic principles and commitments. These principles are foundational. Liberation theology has always considered itself less a body of content, more a fundamental way of going about the discipline of theology. Within the Roman Catholic Church, liberation theology is the first developed theology that is fully historically conscious and reflectively engaged in the process of history. From the beginning, liberation theology has spontaneously bound together theology and ethics, which for various reasons were separated from each other in the modern period. Theology emerges out of praxis and leads back to it. Because of these primordial principles, liberation theology has profoundly influenced Christian theology in the last third of the twentieth century. No Christian theology today can bypass the question of its social situation and the implied beneficiaries of its understandings. The questions and themes raised by liberation theology are now part of the discipline itself.

Libertarianism

In political philosophy 'libertarianism' is a name given to a range of views which take as their central value liberty or freedom. Although occasionally the term is applied to versions of anti-authoritarian Marxist theory (the 'libertarian left'), more commonly it is associated with a view which champions particularly pure forms of capitalism. Libertarians endorse the free market and unfettered free exchange, and oppose paternalistic or moralistic legislation (for example, laws regulating sexual behaviour or the consumption of alcohol or drugs). Liberty, on such a view, is identified with the absence of interference by the state or by others. The legitimate state exists purely to guard individual rights, protecting people and their property from force, theft and fraud. This is the 'minimal state' or 'night-watchman state' of classical liberalism. The state has no authority to engage in the redistribution of property (except to rectify the effects of theft, and so on) or, in certain versions at least, to pursue policies designed to further the common good. Such activities are viewed by the libertarian as illegitimate interferences with an individual's right to do what they wish with their own person or property.

1 Key features of libertarianism

The central issue for libertarianism is the proper nature and justification of the state. Libertarians view the state with great suspicion and are particularly opposed to its attempts to supervise and control people's lives, or to carry out policies in the name of social justice (see Justice). At the same time they assign to individuals strong rights to non-interference and reject the 'collectivist' idea that people can justly be coerced into carrying out society's goals or purposes (see Rights §3). However, in most versions of the theory it is recognized that some central authority - a minimal state - is required to protect citizens from each other and from the intrusions of other states.

All forms of libertarianism assume a 'protected sphere' of strong personal rights to life and liberty. Opinions differ about individual rights to property. The main libertarian camp suggests that just as we have absolute rights of self-ownership, we can also form equally strong rights over external objects. However, left-wing libertarians argue that gross inequalities of property diminish the liberty of the poor. Those who possess no property will live or die at the mercy of the owners of private property. Left-wing libertarians argue that property should be distributed much less unequally or that rights to property should be qualified to achieve this effect (see Property §3).

In response, mainstream (right-wing) libertarians have suggested that the market, insurance and, as a last resort, charity, provide alternatives to state support for the poor. But of greater weight is the libertarian claim that there are certain detrimental consequences of allowing governments to regulate and redistribute property. First, any such system is very intrusive, restricting people's freedom of choice and requiring regular investigation of individual property holdings. Second, it interrupts the efficient running of the market, distorting incentives and price mechanisms. Third, it is counterproductive: government intervention often fails to achieve its aims and has unpredicted and unwanted effects. These are all reasons to avoid state intervention.

Nevertheless a response is owed to the challenge that the poor have very little liberty. Here a distinction between liberty and ability is crucial. There are many things I am unable to do - run a mile in four minutes, for example - which cannot be said to be limitations of my liberty. For a libertarian an individual's liberty is restricted only if some person has reduced the options available, and has done so in a way which violates that individual's rights. So if a person has few options as an unfortunate side effect of the free and legitimate actions of others, then, while their ability to do certain things is restricted, their liberty is unimpeded. But if that person is forced to act at the point of a knife, then their options have been shaped by the rights-violating actions of another; thus their liberty has been violated. On this view, then, economic disadvantage affects ability, not liberty (see Freedom and liberty).

2 Antecedents of libertarianism

Libertarianism, while a relatively recent development, was formed out of several currents. The first is the issue of 'the individual versus the state': libertarians of all ilks clearly wish to give the state only a very narrow authority. The second is the question of what should properly count as the individual's own concern: libertarianism strongly resists the idea that the state should have a role in the regulation of possession and exchange or in the manner in which an individual chooses to live their own life. A third impetus to libertarian thinking, underlining the other two, is the classical liberal tradition, emphasizing the economic advantages of a market free from government

intervention.

In tracing the development of libertarianism, it is important to see the first of these issues - the individual versus the state - as historically prior. Many of the thinkers cited as sources for libertarianism were prepared to accept great restrictions on property holdings. It is the antipathy to a powerful, centralized state that gave libertarianism its initial spur; its transformation into a defence of absolute property rights and extensive market society has been a relatively recent development.

Given these somewhat confusing origins, it is not surprising that various forebears have been claimed for libertarianism. Clearly there are affinities between Locke’s defence of individual property rights and the doctrine of the inviolability of property that forms the heart of libertarianism (see Locke, J. §10). Equally, the classical liberal notion of the *laissez-faire* state, derived from Adam Smith (§4), has had great impact on libertarian thinking. On similar grounds, even David Hume (§5) has, with some justice, been cited as an influence on libertarian thought.

We can also see an overtly anarchist strand in libertarianism, springing from Proudhon and Max Stirner, and reaching twentieth-century individualist thought via the US libertarian Benjamin Tucker (see Anarchism §2). Thus, part of the foundation of libertarianism is an emancipatory politics, formed in radical opposition to Marxism and opposed in particular to Marx’s advocation of a highly structured, authoritarian period of politics prior to the withering of the state (see Marx, K. §12). The anarchist observation that such means would inevitably lead away from the intended end inspired reflection on how a broadly egalitarian society could be organized on truly voluntary grounds. It is something of an irony, then, that such ideas have given rise to a tradition which sometimes, and with good reason, is called anarcho-capitalism.

3 Philosophical foundations

Although it is possible to state a ’core’ libertarian view, many different philosophical foundations for it have been offered. Consequently the details of the views defended have significant differences too: for example, opinions differ about whether libertarians can allow people to opt out of market society into, say, socialism if that is what they prefer. The following, used alone or in combination, are perhaps the most important lines of defence of the doctrine.

The best-known approach, that associated with Robert Nozick (§2), is to try to justify libertarianism in terms of a doctrine of natural rights to self-ownership: as I have the right to determine the course of my own life (provided I respect the similar rights of others), I have no enforceable obligations to others unless I have brought these on myself by my own voluntary action. If a government makes me contribute to the alleviation of the plight of the needy, or forces me to act against my will, then it behaves as if it is part-owner of me, and so violates my right to self-ownership. An important variant of rights-based libertarianism justifies rights not in terms of self-ownership, but in terms of human flourishing. Here the central claim is that only in a libertarian society can a life fully worthy of human beings be achieved.

A second style of justification has greater affinities with consequentialist reasoning. Libertarian society is, at least in part, justified by the economic efficiency of market society. Interventions in the free market are criticized on the grounds that they will impede enterprise, distort incentives and thus diminish the effectiveness of the market. This type of approach does, however, allow some room for guarded government intervention to ensure the smooth running of the market and to prevent the formation of monopolies. The state also has the role of supplying ‘public goods’, in the technical sense, such as street lighting or a pollution-free atmosphere, which the market is notoriously poor at producing. This type of consequentialist libertarianism thus has a reason for permitting certain government activities which would be prohibited by pure rights-based libertarianism.

A third approach tries to justify libertarianism by means of a hypothetical contract. First we posit a hypothetical ’state of nature’ in which individuals, considered as holders of private property, subsist alone or in family groups. It is recognized, however, that social cooperation would produce benefits for all. Accordingly, individuals come together to draw up terms of association. All have a reason to accept legally enforceable rights and duties of non-interference, and, perhaps, duties of emergency aid. However, the rich and powerful, who are in the stronger bargaining position, have reason to resist any more extensive duties, and so this limits the agreement that can be achieved. Nevertheless, certain further functions of governments could be seen as agreed to in this context. In

particular, governments may tax individuals to supply public goods.

A fourth approach takes as its starting point subjectivism about values. In this way libertarianism is represented as the only morally neutral society. A society which redistributes income appears to subscribe to the value of 'need-satisfaction'. But if the wealthy do not accept this value, then to engage in redistribution is to force people to live according to values they do not hold, and so is a form of tyranny. Those who do value the alleviation of others' distress are at perfect liberty to do whatever they want with their own property. But there should be no compulsion to subscribe to this value or to any other.

A fifth approach, less common, is inspired by a point from Kant's moral philosophy. It begins with Kant's distinction between actions performed *for the sake of duty* and actions performed *in accordance with duty* (see Kant, I. §10). If we believe that only the former have moral worth, then an extensive set of legally enforceable duties removes the scope of true virtue: if I am forced to transfer some money to you by law, then, while it may be an action performed in accordance with duty, it has not been done for the sake of duty, but out of coercion, and hence there is no moral worth in my action. This form of libertarianism, then, recommends a slimmed-down state to make virtue possible. (It should be noted that Kant himself did not draw these political conclusions from his moral philosophy.)

4 Problems and criticisms

Libertarians have found themselves struggling with two major problems. First, how can the state be justified? If we cannot show that everyone consents to the state, its existence seems an illegitimate interference with individual liberty. Furthermore, if people make different levels of contribution to the upkeep of the state - some may be unable to contribute, for example - then the state appears redistributive in its nature. Second, libertarianism presupposes that individuals have strong rights to property. But everything that is now owned is constructed out of materials which, once, no individual owned. How can initial appropriation be justified? While strenuous attempts have been made to solve these problems, no consensus has developed. It is worth noting that consequentialist libertarians find themselves in less difficulty on these issues.

In addition to these problems critics have claimed that right-wing libertarians are not entitled to adopt the language of liberty in defence of their view, given the lack of liberty of the poor. This goes hand in hand with a denial that such libertarians have framed the distinction between liberty and ability correctly. Another influential criticism is that one cannot defend powerful individual rights without also accepting a duty to support the extensive social institutions that not only sustain those rights but also give them their point and value. Hence, it is claimed libertarianism is self-defeating. Suffice to say that libertarians strongly contest these points, while pointing out the disadvantages they see with all other systems.

Libertins

The term ‘libertin’ was first used in France in the late sixteenth century as a term of abuse directed against alleged free-thinkers and atheists who were linked with radical Italian philosophers of the previous century. It subsequently came to be associated with a sceptical literary tradition and a group of scholars, philosophers and antiquarians who discreetly ensured the circulation of such doctrines as Epicureanism, Pyrrhonian scepticism, mechanical philosophy, Baconian empiricism and the ‘new’ astronomy. After the disappearance of this group in the middle years of the century, the term came to connote only debauchery and irreverence.

1 ‘Libertins’

The term ‘libertin’ has been used to describe a number of disparate literary, social and philosophical groups in France from the mid-sixteenth to the late seventeenth centuries. It was at one time claimed that libertins were rationalistic atheists who derived their philosophical doctrines from the Averroists of the School of Padua, notably Pietro Pomponazzi and, later, Cesare Cremonini (1550-1630). But this view was subsequently discredited both by those such as Charles Schmitt (1983) who argue that Paduan Aristotelianism was not Averroist in character, and those cultural historians who, like Lucien Febvre (1982), claim that the sixteenth century was an age which found the notion of God indispensable to its systems of thought (see Aristotelianism, Renaissance §5). More recently, libertins have been linked to a tradition of mitigated scepticism which is said to be an essential ingredient of the scientific revolution: but even this thesis, best known through the work of Richard Popkin (1992), has now been challenged.

The word ‘libertin’ emerged in the late sixteenth century as a term of abuse directed at those who were thought to have rejected traditional authority and were indifferent or irreverent in matters of religion. By the 1620s, it was associated with a broad group of sixteenth-century radical thinkers including Pomponazzi, Girolamo Cardano, Giordano Bruno and Tommaso Campanella, many of whom were later to be linked in some way with the authorship of the *Traité des trois imposteurs (Treatise on the three impostors, namely Moses, Jesus and Muhammed)*. In France, the association with scandalous religious opinions was extended to include the imputation of a debauched, hedonistic way of life, taken to be the outward expression of an indifference towards, or denial of, the afterlife; this is the version of libertinage against which the intemperate jesuit François Garasse fulminated in his *Doctrine curieuse des beaux-esprits de ce temps (The doctrine of the over-inquisitive wits of our time)* (1623), and which the mathematician-priest Marin Mersenne impugns in his tract *L’impieté des déistes, athées et libertins de ce temps (The impiety of the deists, atheists and libertins of our time)* (1624). These attacks were stimulated not only by the writings of Giulio Cesare Vanini, a priest who was executed in Toulouse in 1619 for spreading allegedly materialistic doctrines, but also by the behaviour of a free-living group of noblemen in Paris whose acknowledged leader was the protestant poet Théophile de Viau. In his writings, there are hints of Lucretian atomism (see Lucretius), a celebration of sensuality, and, aesthetically, a linking of freedom of thought with freedom of poetic form. Théophile suffered imprisonment and trial in 1623-5; his fate heralded a greater circumspection in libertin circles, which was accentuated further by the stricter regime of the Cardinal de Richelieu (1630-42).

2 The philosopher-libertins

The more philosophical manifestation of libertinage flourished, however, under Richelieu; this is the so-called ‘libertinage érudit’ of the group of scientists, antiquarians, scholars and writers which included Pierre Gassendi, François La Mothe Le Vayer, Gabriel Naudé, Marin Mersenne and Guy Patin. It developed out of the meetings of the unofficial learned academy which met at the house of the Du Puy brothers in Paris. Many of this group shared a passionate commitment to the free exchange of scientific and cultural information at a time when, outside France, the effects of the Roman index of forbidden books and the Inquisition were felt strongly. For this reason, and also because a number of the group were themselves in religious orders, great discretion was shown in their discussion of the new empirical theories of Bacon, Copernican and Galilean astronomy, Epicurean materialism, mechanical philosophy and the ideas of radical Italian thinkers of the previous century (see Bacon, F.; Copernicus, N.; Epicureanism; Galileo, G.). It may well be that certain members of this group were free thinkers. However, it now seems implausible that the group as a whole shared these convictions, even if their discreet behaviour is taken to

indicate that they knew that their discussions were potentially subversive to traditional beliefs.

A number of literary figures whose works have a significant philosophical aspect are associated with this coterie, notably La Mothe Le Vayer. His *Dialogues faits à l'imitation des anciens (Dialogues in imitation of the ancients)* (1630-1) are strongly influenced by Montaigne's brand of Pyrrhonism, and draw inspiration, as does Montaigne, from the writings of the ancient sceptic Sextus Empiricus. Orasius Tubero, the wise sceptical voice in these dialogues, comprehensively discredits religious dogmatism, and even may imply support for atheism: one by one he patiently destroys the traditional arguments for the existence of God, exposes the prejudices in various religious systems, shows these to be inconsistent with each other even on fundamental points (such as whether religious practice is a matter of conscience or outward observance), and deploys Lucretian arguments against the notion of providence. Like Sextus Empiricus and Montaigne, he seems to favour discreet conformism allied with suspension of judgment, which he himself was to practise subsequently when under the patronage of Richelieu and, later still, as tutor to Louis XIV between 1652 and 1660. Most of the other publications of the so-called libertins of this circle appeared in Latin: Naudé's editions of the works of Agostino Nifo and Cardano, Gassendi's life of Epicurus and account of Epicurean philosophy, Mersenne's mathematical works. Between 1648 and 1655, the principal members of the group died, bringing to an end an early but important episode in the development of the *République des lettres*.

After 1661, discussion of the issues which preoccupied these 'libertins' became much more circumspect in the new, increasingly repressive atmosphere of Louis XIV's absolutism; the revocation of the Edict of Nantes of 1685, which took away the religious privileges of Protestants in France, had a yet more drastic effect, as did the persecution of other allegedly heretical religious practices such as Jansenism and Quietism. By the end of the century, the term 'libertin' had become detached from the nexus of connotations which it possessed in 1620; atheism in itself was no longer shocking, provided that discretion was shown in its expression; and it was no longer scandalous to make public one's adherence to the 'new' astronomy. It is therefore not surprising that the term lost much of its colour, and finally slipped, by the middle of the eighteenth century, so that it was a term used only to designate rakes and voluptuaries, whose lifestyle testified to their indifference to religion.

Lichtenberg, Georg Christoph (1742-99)

Lichtenberg was a German mathematician, physicist and astronomer, a highly successful university teacher in the field of experimental physics and a prolific writer of essays on scientific and cultural issues. He was one of the leading public figures of the German late Enlightenment, much admired for his satirical and witty style. Today he is known chiefly for his posthumously published notebooks. In thousands of entries, ranging from a single word to several pages, Lichtenberg recorded observations and thoughts about himself and the world. Only a fraction of those entries belong to the tradition of aphoristic writing developed after Lichtenberg and under his influence. A good proportion of the entries are of philosophical interest. Through the radical form as well as content of the notebooks Lichtenberg has become a contemporary to generations of his philosophical readers.

1 Life

Lichtenberg was born in Oberramstadt near Darmstadt as the seventeenth and last child of a Lutheran pastor. From 1763 until 1767 he studied mathematics, astronomy and natural history at Georgia-Augusta University in Göttingen. From 1767 until 1770 he was a private tutor to three English students, whom he accompanied on their journey home to England in 1770. That same year he was appointed to an extraordinary professorship in the philosophy faculty at Göttingen, charged with the teaching of mathematics and physics. In 1772-3 he undertook astronomical work to determine the longitudes and latitudes of three North German cities, a task carried out in the service of the English king, who was also the elector of the German principality of Hannover. During 1774-5 he spent another sixteen months in England. In 1775 Lichtenberg was promoted to an ordinary professorship at Göttingen, where he remained, with the exception of minor travels in Northern Germany, until his death from lung and heart ailments that had afflicted him for a long time as a result of a rachitic deformation of the thorax.

2 Works

Lichtenberg was not a professional philosopher but exercised considerable influence on later thinkers both within philosophy proper and within the wider sphere of intellectual life. In order to understand Lichtenberg's philosophical significance, a more detailed presentation of the form and substance of his works is indicated.

During his lifetime Lichtenberg's early notoriety and eventual fame rested on his dual activities as a practitioner and teacher of experimental physics and as a popular writer on scientific and broader cultural matters. His main contribution to physics was the discovery of electrostatic phenomena involving the geometrical arrangement of particles on electrically charged plates (known as Lichtenberg figures), a discovery that underlies the twentieth-century development of xerography. Lichtenberg was the first to install a functioning lightning rod in Germany. He took part in scientific debates in probability theory, the physics and chemistry of gases, and meteorology.

In the field of letters Lichtenberg was a prolific and widely recognized essayist. Many of his contributions were satirical treatments of contemporary fashion and foibles. He engaged in several literary polemics, one of them against the widely influential physiognomics of J.K. Lavater, who sought to decipher character traits from facial features as represented in silhouette drawings. Lichtenberg's most successful publications for the general public were the detailed explications accompanying the German and French publication of several series of copper engravings by the English painter and graphic artist, William Hogarth, which appeared between 1794 and 1799.

Lichtenberg would be just another, once highly regarded figure of the German late Enlightenment, were it not for the posthumously published notebooks, which he had kept over some thirty years and which are filled with thousands of entries of many kinds and subject matters, ranging from book excerpts and scientific notes to witty remarks and linguistically and intellectually daring pronouncements on himself and his times. Originally intended as material for future scientific and literary projects, the 'waste books' (*Sudelbücher*), as Lichtenberg ironically called them, provide the reader with a wealth of material that defies systematization and reduction to simple positions. Through their highly original form as well as content, the waste books have exercised considerable influence on the thought and writing of generations of posthumous readers, among them Schopenhauer, Nietzsche, Freud and Wittgenstein.

3 Philosophical outlook

Many of the waste book entries are philosophically interesting as scattered documents of a sustained reflection on the peculiarities, weaknesses and limitations of the human mind revealed in Lichtenberg's own experience. Unlike the writings of ancient and modern moralists, Lichtenberg's observations are not gained or formulated with reference to an overall account of human nature. Rather they should be seen in the contemporary context of the emergence of empirical anthropology and psychology and autobiographical writing with their cultivation of individuality in character and manner of thinking. Lichtenberg's highly experimental, witty as well as daring use of the German language can be regarded as a device designed to approach more successfully the ineffable character of human experience.

A considerable subset of the waste book entries contains reflections on philosophical problems and positions. Yet it would not do justice to the fragmentary nature of this material to reduce it to a body of straightforward views or doctrines. Lichtenberg's philosophical reflections do not add up to a comprehensive or even consistent picture of the world. Compared to the systematic work of academic philosophers of his time, Lichtenberg's thoughts appear eclectic and syncretistic. What is specifically philosophical about Lichtenberg's thinking is not so much its propositional content as its modality: the sceptical attitude, the avowal of a subjective perspective and the tentative character of his reflections, typically expressed by such devices as first-person voice, subjunctive mood and laconic formulation.

Several areas of philosophical inquiry attracted Lichtenberg's thinking, chiefly among those methodological issues in the scientific study of nature and the relation between mind and body. The heterogeneous philosophical remarks are linked by a theoretical as well as practical concern with the nature and limits of human knowledge. Main philosophical influences on Lichtenberg were the German school philosophy, which was part of his university training; British associationist psychology and psychological materialism (David Hartley, Joseph Priestley), with which he became acquainted during his second visit to England; Spinoza's pantheistic metaphysics, which underwent a considerable revival in late eighteenth-century German thought (see Spinoza, B. de); and Kant's critical philosophy, whose principled limitation of human knowledge resonated with Lichtenberg's growing agnosticism about the ultimate nature of soul, world and God in the final decade of his life (see Kant, I.).

In his theory and practice of the sciences Lichtenberg worked under the assumption of the overall unity of nature. He regarded the separation of fields of inquiry and sets of phenomena as a reflection of the limits of human knowledge. He often suggested possible relations between distinct areas of inquiry and their respective domains of objects and cultivated thinking in 'paradigms', whereby the theory of one set of phenomena is used to aid thinking about a different, apparently unrelated set of phenomena. He stressed the heuristic and hypothetical character of the paradigmatic method. For Lichtenberg a systematically unified science of nature was not so much a future possibility as an idea or device for conceptual orientation in the manifold pursuit of knowledge of nature. Especially noteworthy is his sceptical attitude toward the applicability of pure mathematics to empirical reality. Lichtenberg favoured the experimental method as a way to control the unnoticed influence of subjective factors in the observation of nature. He sided with Bacon's contemporary followers (for example, A.V. Haller) and against Newton in supporting the use of hypotheses in the study of nature.

During the 1790s Lichtenberg's thinking was considerably influenced by Kant's theoretical philosophy. Lichtenberg's understanding of Kant focused on the role of human subjectivity in the constitution of knowledge and its objects. He took Kant's restriction of human knowledge to appearances as support of theoretical egoism or the view that all we can really know are our own feelings and thoughts. Lichtenberg did not deny the existence of an independent reality but insisted on its unknowability. In line with his Spinozistic leanings he favoured the thought that the apparent distinction of mind and matter might have an unknowable substratum that is neither of the two.

In further expanding upon Kant's transcendental idealism, Lichtenberg employed different Latin propositions to articulate the distinction between the existential independence of things from us (*praeter nos*) and their spatial externality with respect to us (*extra nos*), arguing that naïve realism consists in the illicit shift from the former to the latter. He inferred that something need not be spatially outside of us in order to be independent from us, thus allowing for the possibility that something might be in us which is yet independent from us. Lichtenberg encapsulated this line of thought in his most famous and influential philosophical aphorism, in which he proposes

to replace the Kantian ‘I think’ with the phrase, ‘it thinks’, to be construed along the lines of the locution ‘it lightens’, thus indicating that the I is not the producer but merely the observer of its own thoughts - an un-Kantian move that was not lost on critics of the autonomy and identity of the thinking subject in nineteenth- and twentieth-century philosophy.

Life and death

Problems concerning life and death are among the most dramatic and intractable in philosophy and they feature in all fundamental areas of philosophical inquiry, especially ethics. Most basic is the problem of what account to give of the value of life itself. This problem has had two main dimensions. One has been the controversy over what precise account to give of death; this has revolved around the issue of whether death is, as it is commonly perceived, an evil, and premature death a tragedy. The other has been the equally puzzling question of how to explain the positive value of life, and to resolve the problem that the more rich we make our account of the value of life, the more the value of life, and hence the nature of the wrong done by killing someone, seems to vary with the quality of the life of the person concerned.

A second set of problems concerns the definition of death and appropriate criteria for death. Death, as the most extreme consequence of violence, also leads one into psychological discussions of aggression and into issues of political violence, terrorism, war and capital punishment in political philosophy. Third, there has been concern with a number of practical moral issues, including abortion and euthanasia. Finally, issues have arisen concerning the relation of the value of the life of persons to other sorts of lives, those of animals, for example, or the life and survival of the ecosystem itself.

This discussion will concentrate on the central themes of the value of life and the harm and wrong represented by death.

1 The value of life

It is not only the evil of death that presupposes that life has value and directs us to account for this value, but also everyday discriminations between lives of different sorts. Even the food of vegetarians involves the premature death of living things, and vegetarians usually accept priorities between different animals and between human individuals at different stages of development. If the hospital is on fire, should we attempt to rescue the patients before the hospital cat, and some patients before others? Should the terminally ill, the very old or those in persistent vegetative state be rescued before or after those with radically different life expectancy and degrees of richness and variety in their lives? Should those responsible for their own poor health (heavy smokers, for example) be preferred to the more prudent? Only an account of the value of life will tell us both why lives should be saved and whether and to what extent it is legitimate to choose between lives.

The chief recent attempts to provide a theory of the value of life have sought to identify those features of the most valuable creatures (humans) which might explain their peculiar value. Most theories combine autonomy, self-consciousness and intelligence as the relevant features (see Autonomy, ethical). Creatures with such capacities have often been termed ‘persons’ (see Persons). Radically different accounts of how to apply such criteria of personhood have emerged. Philosophers of broadly consequentialist orientation have claimed that only creatures who actually possess the relevant characteristics count as persons (see Consequentialism). A major difficulty for such accounts is their counter-intuitive conclusion that creatures which most people do regard as valuable (foetuses and neonates, for example) either are valuable not in virtue of any intrinsic properties that they possess, but only in so far as they are valued by persons properly so called (their parents, perhaps), or will be valuable only in terms of future expected utility.

Others, accepting broadly the same criteria for personhood, have argued that creatures structured to possess such capacities or members of a natural kind that typically possesses such capacities are valuable whether or not particular individuals (foetuses, for instance) actually possess them. Another approach rests content with stipulating that humans are more valuable than others simply in virtue of their species membership. These ‘natural kind’ theorists cannot account for the discriminations people make between the moral importance of, say, foetuses, and other members of the same natural kind. If the life of a mother and her foetus are in danger and both cannot be saved, most would believe it right to prefer the mother.

Philosophers faced with the sorts of problems considered so far often produce *ad hoc*, ‘common-sense’ modifications to their general theories to overcome difficulties with hard cases (see Common-sense ethics). For example, natural kind theorists often admit of grades of natural kind membership, using terms like ‘fully-fledged’

humans to account for differences in attitudes to foetuses and adults.

Ronald Dworkin, in an original account of the value of life, has argued that the sanctity of life must be understood in terms of the waste of investment in life represented by death. Dworkin (1993) distinguishes two dimensions of investment that might be wasted by death: the natural and the human. Natural investment implies that nature itself makes an investment in terms of time, trouble and natural resources when life is created and that investment increases in a linear way as the life continues. In the case of human investment, there is both the investment of the human whose life it is (in terms of self-creation both conscious and unconscious) and that of the other people who invest time, effort and resources in creating and sustaining that life. On this view the wrong of causing premature death is that of squandering this natural and human investment. A conservative view of the wrong of euthanasia and abortion, for example, prioritizes natural investment, while a more liberal view will prioritize a particular interpretation of the human contribution to a life.

This and other accounts suggesting that a life is valuable in proportion to its *richness* give importance to factors which differ across lives. On these views, lives will be more valuable the more the investment in them or the more rich and varied they are. This gives rise to the major problem that no two lives will be equally valuable and huge problems of discrimination between people are inevitable.

2 Criteria for death

Since Epicurus there has been persistent philosophical interest in the problem of accounting for the evil of death (see Epicurus §2). We have already presupposed that this problem can be solved by discussing the value of life. Epicurus' problem is in a sense paradoxical. He made substantially the same point as Wittgenstein: 'death is not an event in life'. If it is not, then there is no one to whom death happens, no one for whom death is an evil. But, of course, most people fear death for the disaster it represents. Epicurus' point turns on the necessity of a harm's being experienced, yet we are all familiar with things we rationally regard as harms whether or not we experience them. I have a rational preference not to fall into a persistent vegetative state even if I will not be aware of this happening and thereafter will never be aware of anything again.

The more interesting and important problems concern the nature of the evil death represents and the importance of defining death, or rather of identifying appropriate criteria for the occurrence of death.

If, as most believe, death is an evil, and premature death a tragedy, and if we can say what makes this so, we will also be answering our first question, about what it is that makes life valuable. Here it is important to distinguish the question, 'What makes life valuable - for you?' from the question, 'In virtue of what is life the sort of thing that can be valuable?' The first question is likely to have as many answers as there are persons to whom it is put, the second question rather fewer.

If we move to the issue of criteria for death we can perhaps see why this is so. Death is as old as life, and people have seldom been at a loss as to when grief is appropriate. In other words, death is not a concept which required elucidation. Traditionally, permanent cessation of breath and/or heartbeat was accepted as a reliable indicator of death. While there may have been some uncertainty as to when cessation could be regarded as permanent, the onset of *rigor mortis* and the decomposition of the body could be relied upon to settle the matter in due course.

Problems arose when technology enabled the heartbeat and breathing of individuals to be maintained almost indefinitely. This was so even when the individuals concerned were otherwise so badly injured as to make it certain both that they would never regain consciousness, and that they would die if mechanical support were withdrawn. But are such individuals *dead*? Why is the question important? Why does it even arise?

Individuals on what is popularly known as 'life support' do not appear dead. They breathe, they are supple and perfused with blood, not cold and stiff like a corpse. In order to justify the cessation of life support (I continue with the popular term because it highlights the paradox we are discussing) with the inevitable consequence that the individual would die, it first had to be clear why it was appropriate to let this individual die, why their life had ceased to be valuable, in the sense of worth saving. Second, the technology of efficient life support narrowly preceded the development of organ transplants. If the individual on life support was to be eligible as an organ donor, their organs had to be in good condition. The condition of the organs was optimized by the maintenance of life support. Finally, pressure created by scarce resources meant that the intensive care beds necessary for life

support were in demand and their occupation by one individual rather than another had to be justified.

The practical way out of the problem was to invent a new set of criteria for the occurrence of death. The idea was not to take individuals off life support and wait for them to die, but to declare them dead while still having their life systems sustained. This could be done if death of the brain were to be accepted as a necessary and sufficient condition for death of the organism as a whole. It is now generally accepted in many different societies and cultures that brain death is the criterion for death of the organism as a whole even though the rest of the organism can be kept ‘alive’ (breathing, blood circulating) after brain death. The major dispute has been over whether whole brain death is necessary for death to be declared to have occurred, or death of the brain stem, the conduit through which all electrical activity in the brain has to pass.

This agreement about brain death is significant, for it surely contains an acknowledgement that it is mental activity, and the things that mental activity supports, that are relevant to the value of life - that when the capacity for consciousness has departed permanently, all that matters has gone. The point of declaring individuals ‘dead’ was to mark the fact that all that matters about an individual had disappeared and that other things of importance could now be permitted. For example, organs could be made available for donation, intensive care beds released for other urgent cases, friends and relatives released from the often considerable burden of care and support, and grief could begin.

The acceptance of brain death marks a change in understanding of what matters about life and at the same time a reassertion of a traditional conception of respect for the sanctity of life and a correlated insistence that only death takes individuals beyond our moral concern. Brain death is such an attractive notion precisely because it permits the preservation of the concept of death as the crucial moral divide and at the same time allows us to think differently of human individuals who yet breathe. However, the artificiality of brain death as a criterion for the death of the entire organism should be borne in mind. There is an important sense in which brain death is at best a new conception of what it is to be dead and at worst an uneasy compromise between facing squarely the issue of what matters about life and harnessing the massive unreflective consensus about the significance of ‘death’.

3 Persistent vegetative state

That this is so can be seen more clearly if we consider the condition of persistent vegetative state, and the landmark judgment by Britain’s House of Lords in the case of Tony Bland. Bland sustained brain damage after being crushed in a crowd of spectators at a football match in 1989, at Hillsborough football stadium in Sheffield, England. The brain damage left him permanently and irrevocably unconscious, in what is now termed a ‘persistent vegetative state’ (PVS). PVS is not fatal; people like Bland can remain alive for thirty or more years. They are not ‘brain dead’. In this they are akin to infants born with anencephaly (absence of a brain) or with their cerebral cortex destroyed.

Bland’s parents, who accepted that their son had ceased to exist in any real - biographical - sense, although his body remained alive, were prevented from obtaining the solace of grief. In desperation, they asked the English courts to declare that it would be lawful for medical staff to withdraw feeding and other life sustaining measures so that their son would die. It is not clear why there was any necessity to take the Bland case to the courts, since it was already well established that there was no obligation to sustain a baby by feeding (*Re C* [1989] 2 All ER 782 and *Re J* [1990] 3 All ER 930).

Eventually the House of Lords ruled unanimously that such a course of action would be lawful (*Airedale NHS Trust* v. *Bland* [1993] 1 All ER 821 H.L.). The problem was, of course, that although Tony Bland had permanently ceased to have ‘a life’ in any meaningful sense, he was not dead and would not die unless the courts permitted doctors to take steps to that end.

A slightly later case was concluded in the Court of Appeal in January 1994. The Master of the Rolls, Sir Thomas Bingham, held, in a bizarre judgment with which the other two lord justices of appeal concurred, that it was permissible for doctors to end the life of a patient by refusing life-prolonging treatment when the consultant and ‘a number of other doctors’ agreed that such a course was in the patient’s best interests and ‘no medical opinion contradicted it’ (*Frenchay Healthcare NHS Trust* v. *S*, Court of Appeal, Judgment, 14 January 1994). Tony Bland’s condition resembled those with brain death in that he had irrevocably lost the capacity for consciousness. The difference is that those in PVS still have electrical activity in the brain and through the brain stem. Does this

difference amount to a morally relevant difference between those in PVS and those who are brain dead? Although the House of Lords was reluctant to change the definition of death, or even address that issue, it is clear from its decision that it thought Bland's life, because he had lost all capacity for consciousness, did not retain the sort of value that required it to be sustained. In the words of Lord Keith of Kinkel in his judgment in that case, 'It is, however, perhaps permissible to say that to an individual with no cognitive capacity whatever, and no prospect of ever recovering any such capacity in this world, it must be a matter of complete indifference whether he lives or dies'.

There was no question in Bland's case of competing claims on the resources required to sustain him, so that the decision to permit a course of action designed to achieve the death his parents sought was a deliberate, conscious decision to end his life. A hotly debated question is whether such a decision constitutes a form of euthanasia. Although the House of Lords strongly denied that this is what it was doing, its decision in the Bland case was thought by many to legalize, for the first time in the United Kingdom, a form (albeit very restricted) of euthanasia. That the case of Tony Bland establishes a precedent for legally sanctioned euthanasia in the United Kingdom is confirmed by the words of Lord Mustill in his judgment in that case:

> The conclusion…depends crucially on a distinction drawn by the criminal Law between acts and omissions, and carries with it inescapably a distinction between, on the one hand what is often called "mercy killing", where active steps are taken in a medical context to terminate the life of a suffering patient, and a situation such as the present where the proposed conduct has the aim for equally humane reasons of terminating the life of Anthony Bland by withholding from him the basic necessities of life. The acute unease which I feel about adopting this way through the legal and ethical maze is I believe due in an important part to the sensation that however much the terminologies may differ the ethical status of the two courses of action is for all relevant purposes indistinguishable.

The key features of Lord Mustill's judgment are, first, the acknowledgement that the course of action requested of, and approved by, the courts 'has the aim…of terminating the life of Anthony Bland'; and, second, that the supposed difference between acts and omissions relied on by the common law tradition to make moral and legal distinctions, characterizes two courses of action that are ethically 'for all relevant purposes indistinguishable'. This decision made the United Kingdom the second country in Europe to have judicially recognized the necessity of bringing to an end the lives of at least some innocent individuals who have not requested death. The Netherlands legalized euthanasia under certain conditions in a High Court case decided in 1984 and later formally enshrined euthanasia in its legal system.

It is important to emphasize the proviso 'who have not requested death', for other instances of courts defending the right to die have turned on precisely this issue. The landmark United States case concerning PVS, that of Nancy Cruzan, depended crucially on whether Cruzan had expressed a wish to die prior to falling into PVS, and indeed it is often described as a case establishing the right to die (*Cruzan* v. *Director, Missouri Department of Health* [1990] 497 US 261).

4 The ethics of euthanasia

Arguments about the ethics of euthanasia are essentially the same as, and have been coloured by, arguments about the ethics of suicide. The wrong of suicide has, since the death of Socrates, often been seen in terms of either a violation of some idea of the sanctity of life, or the wrong of depriving a sovereign or a god of the use of a body which was theirs to dispose of. Euthanasia, as essentially assisting suicide, while of contemporary relevance as we have seen, has reawakened the centuries old debate about suicide (see Suicide, ethics of).

Those who defend the legitimacy of euthanasia have three main approaches to defending the ethics of what they propose. First, some see euthanasia (like suicide) as a dimension of human freedom and argue that the value represented by respect for autonomy is incomplete unless it encompasses the limiting case of suicide or assisted suicide. On this view, no further justification is required. The second view is based on compassion and tends to undermine this purist approach to the ethics of euthanasia. It argues that suicide and euthanasia are legitimate ways of bringing to an end suffering which cannot be adequately controlled or ended in any other way. This approach can undermine autonomy because it lapses if there is an equally effective way of controlling the pain and suffering. The third type of defence of euthanasia is exemplified by Ronald Dworkin's account (see §1), which argues that

respect for the intrinsic value of life, properly understood, sees life essentially as meaningful and valuable because of the shape given to it by the individual whose life it is, and that this shaping power must include control over life's end. Unlike the first defence of euthanasia which appeals simply to autonomy, Dworkin's approach places autonomy at the service of, and hence subordinate to, a conception of the intrinsic value of life. On this view it is not all autonomous decisions to end life that are justified, but only those which conduce to the agents own conception of what it is that makes their life make sense.

Arguments against the legitimacy of euthanasia take two forms: they take a stand on principle or they attempt to undermine the cogency of the arguments in favour of euthanasia. The principled approach either harkens back to the idea that an individual's life is not theirs to dispose of, belonging to the sovereign or the deity or both (one via the other), or takes a stand on the sanctity of life. The more pragmatic approach tends to suggest that the freedom to end one's own life is not part of autonomy properly understood, or that there are other compassionate and effective ways of controlling pain, both physical and psychological.

It is difficult to resolve the differences over euthanasia when the issue is one of principle. Perhaps the most obvious reconciling strategy is to seek cases in which those opposed to euthanasia would concede the legitimacy of killing, and ask if related justifications might not hold good in the case of euthanasia. For example, not all opponents of euthanasia are pacifists, and even pacifists might understand extreme exceptions to the rule against killing the innocent.

One test might be how people feel about the following case. A lorry driver is trapped in the blazing cab of his vehicle following an accident. A policeman is on the scene and sees that the driver cannot be extracted before the flames get to him and he is burned alive. The policeman can let him be burned alive or can give him a quick and relatively painless end by shooting him in the head. The driver says, 'Please shoot me; do not let me be burned alive!' Those opposed to euthanasia in all circumstances must give one answer to the policeman's dilemma, those in favour will give the alternative.

There is one final sort of objection to euthanasia. It avoids the policeman's dilemma but has its own problems. Some people are not opposed to euthanasia on principle and would permit it in exceptional cases, like the policeman's dilemma. However, they regard it as constituting a 'slippery slope' which if permitted would lead to unacceptable forms of killing. They therefore object to the *legalization* of euthanasia, but can cope with isolated and exceptional instances, by forgiveness rather than by justification. The question advocates of the slippery slope objection must answer is whether it is reasonable and rational to criminalize behaviour they admit to be both moral and defensible, and whether or not the unacceptable levels of the slope can be guarded against in another way.

5 Contraception and infanticide

Contraception raises issues of life and death analogous to those we have discussed. First, there are methods of contraception which operate to effect early abortion by, for example, preventing implantation of a fertilized egg. Second, those who regard the potentiality argument as giving moral status to the foetus will, if they are consistent, see contraception as one way in which potential human beings have their potential frustrated. There is, of course, another dimension to the ethics of contraception which is not related straightforwardly to issues of life and death. That is where one sexual partner conceals from the other the nature, existence and/or reliability of the methods of contraception used or leads the other partner to believe a method of contraception is being used when it is not (see Truthfulness).

Since the advent of HIV/AIDS, a popular method of contraception has become more significant as a barrier to infection, and this has added to the moral responsibility of using one particular method of contraception. Questions are often raised as to whether someone who uses no method of contraception, or fails to use a condom, is willing to conceive and bear the responsibility of a child or is willing to run the risk of HIV infection.

It is sometimes suggested, particularly by Catholic thinkers, that contraception subverts the purpose of sex, which supposedly was designed by the deity for procreation. This is a curious argument, however, because if sexual relations are wrong except when they could conceivably result in procreation, then sex between infertile people or during pregnancy is wrong. If on the other hand it is practices which weaken the prospect of new people coming into existence which are to be avoided, then it looks as though it is a celibate priesthood, or the existence of nunneries, which are an affront to God's purpose.

Infanticide raises special moral problems only for those who see a morally relevant difference between the foetus and the neonate. If abortion is permissible, infanticide will surely be permissible on the same terms, unless the newborn differs in some relevant way from those foetuses the abortion of which is permissible. Attempts have been made to identify such differences in three main ways: in terms of either some capacities possessed by the newborn and not the foetus, or the newborn's supposedly greater potential for personhood, or the social relations it forms for the first time on consciously encountering other beings. All of these alleged differences are controversial, and we should note that the last, socialization, leaves unprotected any and all unloved, unwanted and unclaimed infants (see Reproduction and ethics).

Life, meaning of

This is an obscure yet central topic in philosophy. Often associated with the question whether human beings are part of a larger or divine purpose, the question, 'What is the meaning of life?' seems to invite a religious answer. Much philosophical discussion, however, questions the necessity of this association. Attention to the inevitability of death has often seemed to make life's meaning problematic, but it is not obvious how immortality could make the difference between meaning and its absence. The theme of absurdity runs through much discussion of those who believe the universe to be indifferent. Though our lives have no significance, they argue, we must live as if they do. In the face of this absurdity, some advocate suicide, others defiance, others irony. One may also turn away from the issue of cosmic significance, and look for meaning elsewhere.

1 The meaning of 'the meaning of life'

The question, 'What is the meaning of life?', probably arouses both more contempt and more respect for philosophy than any other. On the one hand, the question is notoriously vague and has encouraged much pompous nonsense. On the other, the urge to understand the point of our existence is deep and pervasive, and is indicative of qualities of mind that are arguably central to being human.

A major difficulty besetting the topic is lack of clarity about the subject itself. Drawing comparisons with other contexts in which we ask for meanings tends to increase confusion. When we ask for the meanings of words or phrases, we ask what they are typically used to communicate. Life, however, is not an item in a system of communication. It does not seem to be used or intended to represent something beyond itself. In certain circumstances we also talk about the meaning of nonlinguistic items: footprints mean someone else has been here; a rash on the skin means the child has measles. Analogies with these uses of 'meaning', however, have not proved helpful.

Religion, particularly Judaeo-Christianity, provides a natural context for the question of the meaning of life (see Religion and morality). If one believes that a supernatural being created the world with some grand design, the question asks for the purpose of that design or the place of life within it. However, the philosophical topic of the meaning of life - or the set of overlapping topics that have come over time to be associated with the phrase - cannot be restricted to issues that make sense only on religious assumptions.

Central concerns that come under the topic include questions about whether life has a purpose, whether life is worthwhile, and whether people have any reason to live, independently of their specific circumstances and interests. Any of these questions may be asked about life, or, more commonly, about human life, but they can also be asked about individual lives, particularly about one's own life. We can search for purposes, reasons, values that are acceptable from points of view external to ourselves, or we can restrict our attention to the realm of desires and goals found in our psyches or our communities, indifferent to possible perspectives beyond the human. Although the phrase 'the meaning of life' seems to assume only one meaning to life, we may be led to reject this assumption without concluding that life is meaningless. Often, the focus of the question shifts in the very process of trying to answer it.

To inquire into the meaning of life, then, is like engaging in a search in which you are not sure quite what you are looking for until you find it. Any attempt to give an unambiguous paraphrase of 'the meaning of life' is bound, like the phrase itself, to foreclose certain options and cut off paths of inquiry that should not be ruled out in advance.

2 The relevance of death

The sense that there is a problem about the meaning of life is frequently brought on by the contemplation of death (see Death §8). Indeed, it is often thought, as it was by Schopenhauer (1851) and by Tolstoi (1886), that the question arises precisely because our lives will end in death (see Schopenhauer, A. §6). However, as some philosophers have noticed, the connection between our finitude and life's meaning is puzzling. If the assumption that we will all die makes life seem meaningless, how would the opposite assumption - that we will live forever - make the situation any better?

A possible explanation for the connection between the thought of death and the fear that life is meaningless is that

facing up to one's own mortality destroys one's prospects for happiness. If ultimate happiness were likely or even possible, we might not feel the need for meaning - one does not need a reason to live as long as living is fun, and the aim of achieving ultimate happiness, were it attainable, might be purpose enough. For some, however, the knowledge that they will die makes happiness impossible. Somewhat differently, recognition of the inevitability of the death of one's culture and one's species as well as of oneself may make the interests and goals one formerly had appear worthless or silly.

Again, belief in a God can provide relief from these concerns. The promise of an afterlife, in which at least some achieve eternal bliss, renews the possibility of working towards ultimate happiness. Independently, the existence of an eternal and superior being who cares about us and about what we make of our lives relieves the worry that our goals and our conduct are insignificant.

3 Absurdity

If God does not exist, many argue, then human life is absurd. The human condition, these philosophers claim, would then contain a fundamental and unchangeable disharmony. Albert Camus focused on the clash between our demand that the world be reasonable, orderly and caring and the reality of its being silent, blank and indifferent. Thomas Nagel emphasizes the discrepancy between the objective insignificance of our lives and projects and the seriousness and energy we devote to them. How are we to respond?

Because coming to recognize the indifference of the universe can be a shattering experience, the thought of suicide arises naturally. If all your goals are founded on the assumption that your existence or your actions matter to some entity or process larger and less in need of validation than yourself, the discovery that there is no such entity leaves you stripped of all direction. If, moreover, you think that any direction you take will necessarily reintroduce the assumption you now know to be false, then it may appear that the only option that avoids contradiction is suicide. Camus (1955), however, believed that there is a noncontradictory way of life available. He described 'absurd man' as living 'without appeal', in defiance of the world's indifference to him. Such a person embraces life as fully as possible but without ever forgetting or denying the absence of any rational foundation for it.

Nagel offers a milder response (1971): the recognition of our insignificance is a function of our distinctively human ability to adopt an external view upon ourselves; as such there is no reason to try to deny it or escape from it. At the same time, if our lives are cosmically insignificant, so is the matter of how we respond to this fact. In the light of this argument, Nagel suggests, defiance seems too overblown and dramatic, and irony is more appropriate.

Richard Taylor (1970) draws a different moral from the silence of the universe: the recognition that life is, as it were, objectively meaningless, should convince us to turn our search for meaning inward. The kind of meaning in life that it makes sense to care about is meaning to us. Life has meaning if we are able to engage in activities that we find meaningful. Otherwise, not.

These philosophers all share the view that if there is nothing larger and more intrinsically valuable than ourselves to whom we may see ourselves as positively attached, then life is meaningless in at least one important sense. In this they agree with those who rest a positive view of life's meaning on the existence of a benevolent God. Because they also believe that the condition for meaning is not met and that we none the less must live as if life had meaning, they conclude that human life is absurd. As pointed out by Joel Feinberg (1992), however, there is a difference between a situation's being absurd and a person's being so. By taking a proper attitude towards our predicament, whether that be defiance or irony or some third alternative, we can at least save ourselves from being ridiculous.

It is not clear, however, that we are rationally required to make even this relatively unpessimistic concession to the view that human life is absurd. As we have seen, this view rests on the idea that there is an inescapable clash between what we demand or inevitably presume about our place in the universe and the reality of our situation. But the tendency to want or insist on our cosmic importance may be less deep and inevitable than these philosophers think. Taking life by the horns, pursuing one's projects with energy and devotion, need not rest on delusions of grandeur. It is at least not obvious that when an Olympic athlete strains to the limit in an effort to break a world record, or that when a mother forgoes sleep and comfort to nurse her child back to health, she must believe that her achievement will be of cosmic significance.

4 Subjective and objective meaning

Although discussions of the meaning of life are often associated with considerations about our place in the universe, there are also contexts in which the intelligibility of the contrast between meaningful and meaningless lives appears to be wholly independent of the cosmic issue.

We have already mentioned the view that the kind of meaning it makes sense to care about is subjective meaning. Some, like David Wiggins (1976), believe that a wholly subjective account of meaning cannot do justice to the ordinary use of the term. As Wiggins points out, the idea of a distinction between a meaningful life and a meaningless one is not equivalent to the more obvious and uncontroversial difference between a life that is subjectively satisfying or fulfilling and one that is not. When we wonder whether our lives have meaning, we are not engaged in a wholly introspective enterprise, and when we search for a way to give meaning to our lives, we are not looking for a pill that will make us happy. The life of Sisyphus, condemned by the gods perpetually to roll a stone up a hill only to see it roll down again, has been offered, at least since Camus' writings, as a paradigm of meaninglessness. If we imagine Sisyphus as perversely fulfilled by this repetitious and futile activity, it is not clear whether we would evaluate his life as more meaningful or more dreadful.

Accounts of meaning in life need not be restricted to purely subjective and purely objective alternatives, however. The most natural paradigms of meaningful lives are both abundantly fulfilling subjectively and admirable or worthwhile as judged from points of view external to the agents themselves. The kind of life most comfortably described as meaningful appears to be one in which there is a happy connection between a subject's lively interests and the range of things that are worthy of interest. Meaning seems to arise when subjective attraction meshes with objective attractiveness.

Whether and how this kind of meaningfulness relates to the concern that seems most naturally to call for a connection to some divine or cosmic purpose are difficult issues. Moreover, the notion of 'objective attractiveness' (or objective worth or value), to which this conception of meaningfulness makes reference, is notoriously controversial. Whether such a notion is ultimately intelligible, particularly in the absence of a religious metaphysics, constitutes a major philosophical question on its own (see Moral realism). That the issue of the meaning of life should open onto and connect with other major philosophical issues, however, should come as no surprise. It is, after all, one of the deepest and most basic topics in all of philosophy.

Life, origin of

The appearance of maggots on meat or of intestinal tapeworms supported an ancient belief in the spontaneous generation of life. This idea was challenged in the seventeenth century but not abandoned before Pasteur's experiments. Scientists now agree that terrestrial life had a single origin, but differ in explanations. Some believe that life began with the onset of protein-based metabolism, supported by evidence of spontaneous abiotic amino acid synthesis and theoretical models of self-sustaining and evolving systems of enzymes. Others believe life began with the appearance of nucleic acid-based molecular replicators and have organized their research efforts around the vision of a primordial 'RNA world'.

Aristotle's observation that some life forms 'arise not from living animals but from putrescent matter' went largely unquestioned until the beginning of the seventeenth century. Descartes had no difficulty conceiving of spontaneous generation occurring simply on the basis of matter in motion, though subsequent Cartesian mechanists could not countenance the possibility of life arising spontaneously from nature - construed as passive and without inherent purpose. Their deistic alternative, theories of pre-existence and preformation, endeavoured to attribute all life forms to original acts of creativity. Subsequent generations were deemed to be held in miniature in the germs of their parents and new generations could 'evolve' from the old through the unfolding and elaboration of parts already in place. Committed to an extended regress of miniatures nested inside miniatures the doctrine of pre-existent germs became increasingly vulnerable. Where 'Cartesian matter' lacked the wherewithal to become self-organized, eighteenth-century scientists conceived of a 'Newtonian matter' upon which some uncharacterized force could operate (see Matter). Natural self-organizing capacities were attributed to the existence of 'penetrating forces' shaped by an internal mould (see Buffon, G.L.L. Comte de §3) or by the expansion and resistance of opposing 'vegetative' forces (Needham). Set in motion, the new theories of spontaneous generation were carried into the nineteenth century by both the French *philosophes* and the German *Naturphilosophen* (see Naturphilosophie §3). Where the former opposed a deistic Cartesianism that had become conservative with an uncompromised materialism that could do it all, the latter sought a romantic *rapprochement* of nature and culture, organic and inorganic, within the unity of *Geist*.

Nineteenth-century cell theory resulted in debates over whether cells could arise out of acellular protoplasm as postulated by Schwann (allowing for the possibility of spontaneous generation), or whether cells arise only from other cells (*omnis cellula e cellula*) as proclaimed by Virchow. Scientific opinion became grouped around the poles of mechanical materialism, whose adherents were committed to some form of abiogenesis (life from nonlife), and vitalism (including vital materialism) whose adherents could countenance heterogenesis (life from another form of life) but never abiogenesis (see Vitalism §2). The elucidation of the alternation of life cycles of trematodes led to the demise of any remaining belief in the heterogenesis of parasites from degenerating tissue, and Pasteur's experiments undermined belief in the abiogenetic origins of infusoria. By the end of the nineteenth century, German cytologists too had resolved that not only do cells arise by division from other cells, but even nuclei are never created *de novo*, arising only from previous nuclei. What remained of spontaneous generation was only the conviction of dedicated materialists that there *had* to have been an abiogenetic *origin of life*.

Buttressed by advances in astro-chemistry and cosmogony and a nascent biochemistry of organic catalysis, interest in theories of the origins of life re-emerged in the twentieth century with Oparin and Haldane's visions of a pre-biotic primordial soup from which self-sustaining aggregates of colloidal reactants emerged. Subsequent work proceeded along the lines of an opposition that had already begun to take shape during the 1920s. Whereas Oparin (1924, 1938) and Haldane (1929) looked to the onset of metabolism with an interpretation of life as a *process*, Muller (1929) identified the origins of life with the appearance of an entity, an as yet uncharacterized gene, distinguished by its ability to mutate and self-replicate. With metabolism associated with the catalytic activity of protein-based enzymes, and with genetic replicators (after Watson and Crick (1953)) identified with nucleic acids, that is, deoxyribonucleic acid and ribonucleic acid (DNA and RNA), which serve as templates for their own synthesis, debates about the origins of life have also been construed in terms of 'protein-first' versus 'nucleic acid-first' theories.

Replicator-first theories gained credence from studies by Orgel and Eigen that demonstrated RNA synthesis in

vitro in the absence of either an enzyme or a *prior* template, respectively, and further with the discovery by Cech (1986a, 1986b) of RNA-based catalytic activity. However strong evidence for the abiotic synthesis of nucleic acid *precursors*, or of the ability of RNA catalysts to synthesize arbitrary nucleic acid sequences, has been lacking. Metabolism-first theories gained credence from the studies by Muller that showed that amino acids, the precursors of proteins, may well have been present in an abiotic primitive soup, and from progressively more sophisticated mathematical modelling of the possible dynamics of complex autocatalytic systems.

Aspects of *both* the metabolism first and the replicator first theories can be found in a two-stage model proposed by Dyson (1985) which takes its cue from the dual activity of one small molecule. Adenosine triphosphate (ATP) functions universally in living cells as both the principal intermediary in energy metabolism and as one of the four precursors of nucleic acid synthesis. Postulating the emergence of life as protein-based metabolism, ATP (and perhaps other) nucleic acid precursors may thus be produced biosynthetically as metabolic intermediates. The first nucleic acids would then arise by the chance polymerization of accumulated ATPs. Owing to their ability to serve as templates for further nucleic acid synthesis, these polymers then emerged as intracellular parasites akin to viruses. Dyson hypothesizes a progressive symbiosis between these parasitic replicators, which become stable repositories of polymer information, and the ‘host’ metabolic system which continues to provide nucleic acid precursors.

This two-stage model preserves ontological implications of both points of view. Life appears, first of all, as the holistic cooperativity of complex autocatalytic dynamics, yet remains contingently susceptible to ‘selfish’ short circuiting by ‘born again’ parasitic replicators.

Limbo

According to traditional Roman Catholic teaching, limbo is the postmortem destination of those who have not been baptized, but are not guilty of sin. Lack of baptism bars such people from salvation, but their innocence means that they do not deserve the punishment of hell. They were thought to fall into two groups: the righteous of the Old Covenant, prior to the redemption of Christ, and unbaptized children. The former were supposed to have gone to heaven after Christ's death, but the latter had to stay in limbo forever. The existence of limbo was never dogmatically defined, and it was never given as much attention as heaven, hell or even purgatory, each of which represented a fate which human beings earned in part through personal choice. Nowadays, the possibility that unbaptized babies might be consigned to hell is not widely entertained, and some thinkers hold that the requirement of baptism for salvation is open to interpretation. Consequently, the idea of limbo is not as widely discussed as it once was.

1 History of the idea of limbo

In traditional Roman Catholic theology, limbo is a place for certain of the dead who are deprived of salvation because they have not been baptized, but who do not suffer the punishment of hell. It was usually thought to consist of two distinct parts: a limbo of the fathers (*limbus patrum*), or 'bosom of Abraham', which was a place for the righteous of the Old Covenant who could not enter heaven before the redemption of Jesus Christ; and a children's limbo (*limbus infantium*), which was a place for unbaptized babies and young children prior to the age at which they could commit sin. Such children would be in a state of original sin, but innocent of personal guilt. The limbo of the fathers was said to be empty ever since Christ's descent into hell (limbo) after the crucifixion, when all its inhabitants were transported to heaven, but the babies in the children's limbo were supposed to remain there for all eternity.

There is no mention of limbo in the Bible, and the problem of the fate of unbaptized babies was not addressed until the fifth century in response to the Pelagians, who asserted that God does not deny deceased unbaptized infants eternal life, although they are not in heaven either. The Pelagians maintained that they are in a state of innocence, not damnation, where they experience no pain and have a measure of happiness. Augustine replied that these infants are condemned to hell, but their punishment is much milder than that of adults, and it is preferable to annihilation. Augustine's position seems harsh, but his primary interest in this matter was to use it to get the Pelagians to reveal the heresy at the heart of their doctrine - the denial of original sin (see Pelagianism; Sin §2). The Pelagians' view on infants who die without being baptized was thus a casualty of the debate over original sin. Ironically, their position is very close to the idea of limbo that developed seven centuries later.

In the Greek Church, Augustine's contemporary, Gregory of Nyssa, had written that unbaptized infants neither suffer the torments of hell nor enter the life of the blessed in heaven. Otherwise the Augustinian position was accepted for centuries and was not broken until Peter Abelard argued that unbaptized infants do not suffer the pains of hellfire, but only grief at separation from God. Peter Lombard agrees with Abelard in his *Sentences* (*c.*1145-51), saying that unbaptized infants suffer only 'darkness' in the world to come (*Sententiarum libri quatuor*, lib. II, dist. 33, cap. 2). This development was important because Lombard's *Sentences* became a kind of university textbook, with tremendous influence on subsequent theology. Bonaventure clearly distinguishes between the children's limbo and hell, saying that divine justice establishes children in a state of unchanging love and knowledge, but which is neither joyful nor sad (*Il Sent.*, d.33, a.3, q.2). On the other hand, Albert the Great, who invented the term 'limbo', combines limbo and hell (*De resurrectione*, part 3). Thomas Aquinas took Bonaventure's position, arguing that original sin is not a positive fault, but a privation. Since the punishment must fit the crime it would be unreasonable for God to give a positive punishment for something that is not a positive fault. In arguing against punishment through sensory pain, Aquinas says that if a human being's powers are to be harmed through such pain, the punishment must bear some relation to a fault in the person who used those powers. But there can be no such fault in the case of an infant, so punishment through sensory pain would be unreasonable (*De malo*, q.5, a.3).

The problem of limbo was not handled explicitly by the Council of Trent (1545-63) and subsequently it was treated as an open question. The existence of limbo subsequently became the subject of controversy, with the

Augustinians and the Jansenists denying its existence and the Jesuits defending it. In this century it has been on the decline. It is not mentioned in the documents of Vatican II, the Ecumenical Council called by Pope John XXIII in the 1960s; while *Lumen gentium*, the ‘Dogmatic Constitution on the Church’, mentions briefly the necessity of baptism for salvation, it does not elaborate.

2 The status of limbo in contemporary thought

The limbo of the fathers has never received much attention, presumably because it is now supposed to be empty. The children’s limbo, however, not only poses an obvious theological problem, but also a pastoral one: what should priests tell the grieving parents of a child who dies shortly after birth or, for that matter, in the womb? The proposal that there is a children’s limbo arises out of two suppositions: that there is no salvation without baptism; and that unbaptized babies have made no personal choice whereby they would merit eternal punishment. The limbo of the fathers is predicated on the first assumption together with the assumption that the patriarchs of the Old Covenant would have gone to heaven had they lived after the time of Christ. The compromise position on the souls in these two limbos is that they are deprived of heavenly bliss (temporarily in the case of the patriarchs, and forever in the case of the unbaptized babies), but that they do not suffer. The justification for the limbo of the fathers has obvious extensions to other classes of persons who would have gone to heaven had they been in more favourable circumstances (such as the unbaptized in non-Christian countries), but these individuals were almost always placed in a different category. However, it is not at all clear why their status should not be parallel to that of the inhabitants of the *limbus patrum*. The latter were simply born at the wrong time; the former were simply born in the wrong place. An appreciation of this difficulty and admiration for the virtuous sages of antiquity led Dante, in the *Divina Commedia*, to propose a limbo of the sages, in which Socrates, Plato and Virgil were found. Dante’s poetic power reflects an enduring sensibility, one which has probably outlasted the more traditional theological views on the fate of these people.

It seems odd that the tradition never questioned the assumption that there is no salvation without baptism, but only the assumption that those in limbo do not suffer the pains of hell. However, the concept of baptism was sometimes interpreted broadly enough to include some persons who had not actually gone through the sacramental rite. Aquinas proposed two categories, Baptism of Blood and Baptism of Desire, to handle some of the problematic cases, and there were frequent appeals to these categories in Catholic theology until Vatican II. It is even possible to interpret baptism so widely that it applies to everyone. For example, Bruno Webb (1953) has suggested that death itself might be a kind of sacrament from which the saving power of baptism arises. It has become increasingly common, however, simply to dispute the requirement of baptism for salvation. Among Protestant philosophers, Jonathan Kvanvig (1993) has argued that there is no good reason for the doctrine of limbo, since it arises from a combination of a very severe conception of hell and a very restrictive conception of how it is possible to reach heaven.

The idea of limbo has therefore fallen into disuse, not because it is generally thought that the inhabitants of limbo are really in hell, but because it is often thought that they are in heaven. Moreover, the coherence of the concept has also been questioned. Ladislaus Boros argues that the notion of an exclusion from the human being’s proper and intended end that is nevertheless not experienced as suffering is self-contradictory (see Hick 1976). More and more, there is doubt that baptism is essential for salvation, so there is a growing tendency to reject the primary assumption of the dilemma which the existence of limbo was intended to resolve.

Linear logic

Linear logic was introduced by Jean-Yves Girard in 1987. Like classical logic it satisfies the law of the excluded middle and the principle of double negation, but, unlike classical logic, it has non-degenerate models. Models of logics are often given only at the level of provability, in that they provide denotations of formulas. However, we are also interested in models which provide denotations of deductions, or proofs. Given such a model two proofs are said to be equivalent if their denotations are equal. A model is said to be 'degenerate' if there are no formulas for which there exist at least two non-equivalent proofs. It is easy to see that models of classical logic are essentially degenerate because any formula is either true or false and so all proofs of a formula are considered equivalent. The intuitionist approach to this problem involves altering the meaning of the logical connectives but linear logic attacks the very connectives themselves, replacing them with more refined ones. Despite this there are simple translations between classical and linear logic.

One can see the need for such a refinement in another way. Both classical and intuitionistic logics could be said to deal with static truths; both validate the rule of modus ponens*: if* $A \to B$ *and A, then B; but both also validate the rule if* $A \to B$ *and A, then* $A \wedge B$*. In mathematics this is correct since a proposition, once verified, remains true - it persists. Many situations do not reflect such persistence but rather have an additional notion of causality. An implication* $A \to B$ *should reflect that a state B is accessible from a state A and, moreover, that state A is no longer available once the transition has been made. An example of this phenomenon is in chemistry where an implication* $A \to B$ *represents a reaction of components A to yield B. Thus if two hydrogen and one oxygen atoms bond to form a water molecule, they are consumed in the process and are no longer part of the current state. Linear logic provides logical connectives to describe such refined interpretations.*

1 Syntax

Given these new interpretations of implication and conjunction, they are given new symbols: '$\multimap$' and '$\otimes$', respectively. Thus the chemical reaction mentioned above would be given symbolically as $(\mathrm{H} \otimes \mathrm{H} \otimes \mathrm{O}) \multimap \mathrm{W}$.

Despite the appeal of these refined connectives it is clear that our logic is very weak: a formula can be used once only (hence the term 'linear'). To describe situations of static truths, where formulas can be reused (that is, allowed to persist) or ignored, we introduce a new logical connective '!' where $!A$ means that the formula *A* may be used as many times as needed (including zero). Thus the traditional notion of implication can be simulated by $(!A) \multimap B$. This idea leads to simple translations of both classical and intuitionistic logics into linear logic.

Given two transitions $A \multimap B$ and $A \multimap C$, we clearly have the transition $(A \otimes A) \multimap (B \otimes C)$, but not $A \multimap (B \otimes C)$. However, we shall define a new transition $A \multimap (B \mathbin{\&} C)$, which represents the superimposition of the two transitions. It represents a choice of the resulting state *B* or *C*. Despite its disjunctive feel the connective '$\&$' is really a conjunction - both states are being offered but only one may be chosen, via one of the axioms $(A \mathbin{\&} B) \multimap A$, $(A \mathbin{\&} B) \multimap B$. Consequently linear logic has two forms of conjunction, one ($\otimes$) where the initial states are disjoint and one ($\&$) where they are identical. The former is known as a multiplicative connective and the latter as additive. Symmetrically linear logic has two forms of disjunction, the multiplicative form written '$\star$' and the additive form written '$\oplus$'.

Linear formulas are built up from a collection of (positive and negative) atomic formulas, written p and $p^{\perp}$, by means of the multiplicative connectives, '$\otimes$' and '$\star$', additive connectives, '$\&$' and '$\oplus$' and the so-called exponentials, '!' and its dual '?'. The connectives have units (in the sense that in classical logic true (T) is a unit for conjunction ($\wedge$), as $A \wedge \mathrm{T} \equiv A$): two multiplicative units, 1 and $\perp$, and two additive units, $\top$ and 0; such that $A \otimes 1 \equiv A$, $A \star \perp \equiv A$, $A \mathbin{\&} \top \equiv A$ and $A \oplus 0 \equiv A$. (The logical symbols used here match Girard's rather idiosyncratic selection, apart from '$\star$' which Girard writes as an upside-down ampersand.)

As with classical logic, negation, written $A^{\perp}$, is a defined notion given inductively over a composite formula. This is given by:

$$(p^\perp)^\perp \text{ is } p$$
$$(A \otimes B)^\perp \text{ is } A^\perp \star B^\perp$$
$$(A \star B)^\perp \text{ is } A^\perp \otimes B^\perp$$
$$(A \mathbin{\&} B)^\perp \text{ is } A^\perp \oplus B^\perp$$
$$(A \oplus B)^\perp \text{ is } A^\perp \mathbin{\&} B^\perp$$
$$1^\perp \text{ is } \perp$$
$$\perp^\perp \text{ is } 1$$
$$\top^\perp \text{ is } 0$$
$$0^\perp \text{ is } \top$$
$$(!A)^\perp \text{ is } ?(A^\perp)$$
$$(?A)^\perp \text{ is } !(A^\perp).$$

Also as with classical logic, we are able to define an implication using negation and disjunction: thus $A \multimap B$ is $A^\perp \star B$.

Gentzen's sequent calculus (see Natural deduction, tableau and sequent systems §2) is a tool for studying various rules of logics. Sequents are written $\Gamma \vdash \Delta$, where Γ $(= A_1, \ldots, A_n)$ and Δ $(= B_1, \ldots, B_m)$ are finite sets of formulas. The traditional reading of such sequents is that $A_1 \wedge \ldots \wedge A_n$ implies $B_1 \vee \ldots \vee B_m$. In the linear setting it says that $A_1 \otimes \ldots \otimes A_n$ implies $B_1 \star \ldots \star B_m$. However, we can employ a shorthand by considering only sequents of the form $\vdash \Delta$, where general sequents of the form $\Gamma \vdash \Delta$ are simulated using $\vdash \Gamma^\perp, \Delta$. The main rules are as follows.

$$\frac{}{\vdash p, p^\perp} \quad \text{(identity)}$$

$$\frac{\vdash \Gamma, A \qquad \vdash A^\perp, \Delta}{\vdash \Gamma, \Delta} \quad \text{(cut)}$$

$$\frac{}{\vdash 1} \quad (1) \qquad \frac{\vdash \Gamma}{\vdash \Gamma, \perp} \quad (\perp)$$

$$\frac{\vdash \Gamma, A \qquad \vdash \Delta, B}{\vdash \Gamma, \Delta, A \otimes B} \quad \text{(tensor)}$$

$$\frac{\vdash \Gamma, A, B}{\vdash \Gamma, A \star B} \quad \text{(par)}$$

$$\frac{\vdash \Gamma, A \qquad \vdash \Gamma, B}{\vdash \Gamma, A \mathbin{\&} B} \quad \text{(with)}$$

$$\frac{\vdash \Gamma, A}{\vdash \Gamma, A \oplus B} \quad (\text{sum}_1)$$

$$\frac{\vdash \Gamma, B}{\vdash \Gamma, A \oplus B} \quad (\text{sum}_2)$$

The difference between the multiplicative and additive connectives can be seen quite clearly by comparing the 'tensor' and 'with' rules. As is the case normally, writing the sequents in a two-sided fashion, and restricting the right-hand side so as to contain at most one formula (for example, $\Gamma \vdash A$), results in the so-called intuitionistic fragment of linear logic. It should be noted that some of the connectives are not available in the intuitionistic fragment. The sequent calculus formulation enjoys the important metatheoretic property of cut elimination (Gentzen's *Hauptsatz*), that is, there is an algorithm which rewrites any proof into one which does not make use of the 'cut' rule.

Girard also showed how one may refine the sequent calculus formulation further by replacing the sequents with graphs. Thus formulas become nodes and applications of the rules become methods for transforming graphs. For

example, the ‘identity’ rule is replaced with two nodes (p and $p^{\perp}$) and an arc between them, whereas the tensor rule takes the two nodes *A* and *B* and places arcs between them and a new node $A \otimes B$. These graphs are known as ‘proof nets’. Several sequent proofs are represented by a single proof net and so one may think of proof nets as revealing the essential inner structure of a linear logic proof.

2 Models

An important feature of linear logic is that its models need not be degenerate, in the sense given earlier. This is in contrast to classical logic. Using the mathematical language of category theory it is relatively easy to describe abstractly which structures are necessary for a model of linear logic: essentially they form particular categories first identified in the 1970s by Barr (see Barr 1991; Category theory, introduction to). A further problem is to construct concrete models, which are ideally complete (that is, they contain only denotations of provable formulas and valid deductions).

Girard offered two models of linear logic in his seminal 1987 paper. The first, ‘phase spaces’, is a model based on a certain sort of algebraic structure. The second, ‘coherent spaces’, is a graph-theoretic model. A large number of different models have since been identified and again it should be stressed that all of these models are non-degenerate.

An appealing model was given by Blass (1992), based on earlier work on constructive logic by Lorenzen. Here the meaning of a proposition *A* is given by specifying a game, or dialogue, between two players, one of whom is trying to assert *A* and the other refute it. Thus a proposition is interpreted as a game and validity by a winning strategy. The connectives can then be understood as operations on games. For example, the connective ‘ $\otimes$’ is interpreted as an operation which interleaves two disjoint games or, in other words, plays them side by side. These refined notions of games have been the subject of some intensive work. Despite this effort, and the intuitive appeal of the approach, these models suffer from being incomplete - they validate additional axioms, mostly ‘weakening’: $A \multimap 1$. Some models validate an additional axiom, known as ‘mix’: $(A \otimes B) \multimap (A \star B)$. The status of this axiom (which can also be given as a sequent calculus rule) is uncertain but may be decided by a convincing (game) model. Indeed providing a convincing complete model still remains an open problem.

3 Decidability

One can gain a useful insight into a logic by considering how difficult it is to decide whether a given formula is provable in that logic. Most first-order logics are undecidable but there is considerable variety when considering propositional logics. Both propositional classical logic and propositional intuitionistic logic are decidable albeit with differing complexity ($\mathcal{NP}$-complete and $\mathcal{PSPACE}$-complete, respectively; see Complexity, computational §4). Given that we can encode both these logics into linear logic one might expect linear logic to be decidable. Surprisingly it has been shown that propositional linear logic is undecidable. Indeed even the intuitionistic fragment of linear logic is undecidable. A considerable amount of work exists considering the decidability and complexity of various fragments of linear logic obtained by selecting a subset of the connectives and units.

4 Applications

As linear logic is a refined version of both classical and intuitionistic logic, it is not surprising that it has been applied to many areas of mathematical logic and theoretical computer science. Linear logic’s refined connectives and notion of proof offer a new understanding of classical logic’s connectives and proof deductions. In particular the notion of proof dynamics - the process of cut elimination mentioned in §1 - can be studied with improved accuracy using proof nets. As there are simple translations from classical to linear logic, it is possible to use the non-degenerate models of linear logic to tease out non-degenerate models for classical logic. Many researchers refer to this process as the extraction of the ‘constructive content of classical logic’.

Logic is used by computer scientists in many ways to represent computation. One method is to represent a program as a proof and computation as the process of simplifying the proof or, in other words, bringing it to a normal form (see Computability theory §3). Another method is to represent a program as a set of rules and a goal, and computation as the process of searching for a proof of the goal given the rules. Given its refined nature, linear logic sheds new light on both these methods.

Importantly, deriving from some of the ideas of the game models described in §2, linear logic appears naturally to encode a process of computation which is inherently parallel in nature. Realizing this process and relating it to existing models of parallel computation is another important open area.

Linguistic discrimination

'Linguistic discrimination' is a redundancy. Discriminating is at the heart of what languages do. The question, of course, is when they can be said to do it invidiously, or rather when we, in our use of language, can be said to be discriminating invidiously. In Aristotelian terms, the proper use of linguistic discriminations is to make the right sort and number of discriminations in the right ways and at the right times - that is, not to discriminate between those things that, for the legitimate purposes at hand, ought to be seen as the same; to discriminate between those things that, for the legitimate purposes at hand, ought to be seen as different; and to discriminate in ways that advance legitimate and not illegitimate purposes. Disputes about what constitutes linguistic discrimination (in the invidious sense) revolve around both the legitimacy of our purposes and, in the light of those purposes, the aptness of particular discriminations. Such disputes presume both that our language shapes our actions (that linguistic discrimination plays a role in maintaining unjust inequalities) and that our actions can shape our language (that acknowledging such discrimination can and should lead to linguistic change).

1 Arguments for causality and remediability

Claims for the causal efficacy of linguistic discrimination range from the claim that some thoughts are made either unavoidable or impossible because of the language in which thinking occurs, to the claim that language shapes, without determining, how we think. The stronger claim, often appealing to the Sapir-Whorf hypothesis, sees language as providing the conceptual tools without which the experienced world is inchoate and only in terms of which can sense be made (see Sapir-Whorf hypothesis). In its strongest form, this hypothesis is surely false: language-users are inventive, and all languages have room for invention.

It is harder to refute the view that the languages we use shape our thoughts, making some ways of thinking more 'natural', more readily comprehended by our interlocutors, harder to avoid if they come to seem problematic. Richly nuanced vocabularies exist to describe some parts of the experienced world and not others. Nor are all the differences semantic: Black English is less well suited than is Standard English for expressing the agentless passive, that is, the idea that 'it happened' without indicating that someone or other did something (Jordan 1985).

That the language we use does not absolutely constrain us is no reason not to attend to the ways in which it shapes our thinking, leading us to imply what we do not intend, or making it difficult for us to say what we mean, or what we would mean if we had the words to mean it with. It is also remediable. Languages constantly change in response to an indefinite range of social forces; and while there can be no guarantee that a suggested reform will catch on, there is no reason a priori to argue that it could not do so. One may choose to resist it, but that choice is as political as is the argument for change.

2 Taxonomic schemes

Metaphysicians have long debated the nature of kinds. Are some of them 'natural' (whatever that means)? Are only such kinds, if there are any, 'real'? What about kinds created by our taxonomizing practices? Inspired largely by the work of Michel Foucault, theorists are examining the social and political contexts within which taxonomies operate and the value judgments they both depend on and reinforce (see Root 1993). Case studies explore the social construction of race (Goldberg 1990) and gender (Lorber 1994); as well as of kinds of practices such as sexual harassment (MacKinnon 1979) and child abuse (Hacking 1992), conditions such as premenstrual syndrome (Zita 1988), life stages such as childhood (Aries 1962), and persons such as homosexuals (Stein 1992) and heterosexuals (Katz 1990). Questions about invidious discrimination arise with respect to kinds that arguably rest on dubious science or on politically questionable social practices.

Thus racial classifications have been argued to be discriminatory because they are biologically unfounded, on the assumption that races, if 'real', are so because of discoverable biological differences between different racial populations. Since there appear not to be such differences, racial classifications distinguish as different those who, on the alleged basis, are in fact the same. Alternatively, it can be argued that race is best understood as a social classification, in which case the issue is whether as such race can be made coherent and, if so, whether the social practices that make it coherent are just. If racial classification cannot be made coherent, then it is discriminatory for distinguishing between people who, on its own terms, are not distinguishable; if it is coherent but grounded on

unjust social practices, then racial classification would be invidiously discriminatory because it was wrong to engage in the practices that make it descriptively correct. Others argue that, although founded on racist practices, racial classification has acquired a conceptually adequate grounding in practices that include those of anti-racist resistance and positive group identification (see Race, theories of). Similar questions are raised about the classifying of persons as homosexual or heterosexual: apart from social practices of stigmatizing homosexuality as unnatural, perverse or sick, what reasons are there for classifying persons according to whether they desire those of the same or the opposite gender (see Sexuality, philosophy of)?

The situation is somewhat different regarding discrimination by gender (see Language and gender). There is better reason than in the case of race to regard the distinction between males and females as grounded in biology, although it is a matter of dispute whether the social practices that at the very least build upon, extend and ‘clean up’ the biological differences are morally and politically justifiable. But there is a further question: gender ascription, in English and in many other languages, is uniquely non-optional, in particular because of the gender inflection of pronouns. This ubiquitous marking of gender is arguably discriminatory, implying that, unlike all the other equally real differences between people, gender is ubiquitously relevant. (Similarly, the argument for the use of ’Ms’ rests not on the wrongness of distinguishing between unmarried and married women but on the wrongness of requiring that such a distinction be marked whenever a woman is referred to by title.) Ubiquitous gender-marking is part of the social construction of gender, both in making gender neutrality difficult to express even when it is agreed to be appropriate and in making gender ambiguity socially stigmatizing even when it is acknowledged to be possible.

3 The paradigmatic and the generic

Semantic spaces are complex: not all unquestionable members of a class are equally paradigmatic. It seems to be a feature of human cognition to learn categories by grouping members around paradigmatic exemplars, and variation in paradigms is not for the most part idiosyncratic. It is a matter of dispute how much of the contouring of semantic space is ’hard-wired’, but it is clear that for at least many categories, paradigmatic exemplars owe that status to culturally variable, frequently unjust, social arrangements.

Thus, it has been pointed out (Spelman 1988) that within racist cultures, white people are paradigmatic and people of colour are variously ’different’, so that even anti-racist arguments claim that for all relevant purposes, people of colour are ’just like’ white people. Similarly for other forms of privilege: those who are, for example, male or middle-class or heterosexual are paradigmatic in the sense that their achievements, interests and needs are taken as the measures against which those of others are evaluated. When, however, the category is itself a subordinate one, paradigmatic exemplars are likely to be members of a relevantly subordinated group. In either case, those who conform to the paradigm are typically ’unmarked’, while those who are not paradigmatic are ’marked’: ’male nurse’, ’gay author’.

It is a matter of controversy the extent to which such language is itself discriminatory, rather than just accurately reflecting reality. The arguments for claiming specifically linguistic discrimination point out that being in the majority and being paradigmatic are not always the same thing and, even when they are, linguistic discrimination helps to maintain, rather than innocently reflecting, social discrimination.

A limiting case of the paradigmatic is the false generic. False generics are terms for the paradigmatic members of a group improperly used to refer to all members. It has been a matter of controversy whether in English masculine nouns and pronouns are also, ambiguously, genuinely generic, or whether they should be regarded as false generics. The arguments for the latter position are both linguistic and political. Linguistic arguments (see Mercier 1995) point to the often irresolvable ambiguities that result from the employment of the masculine as generic, as well as to the anomalous and illogical rules that govern such employment. Political arguments point to the advantages that accrue to those who are taken to be generically human, rather than ’different’, and to the alienation increasingly experienced by female listeners and readers uncertain of the extent to which, if at all, they are included among the ’men’ under discussion.

4 Stereotyping and stigmatizing

Another type of linguistic discrimination concerns the vocabulary used to refer to members of privileged and

subordinated groups and, by analogy, parts of the nonhuman world that are variously associated with them. Tropes of light and darkness, for example, are central to European discussions of reason, especially those that were articulated concurrently with the colonization of Africa - the ’dark continent’ - to which Europeans had the right and duty to bring ’enlightenment’. Gender stereotypes permeate talk about ’mother’ nature, the ’hard’ versus the ’soft’ sciences, ’active’ reason versus the ’passions’. Such vocabulary relies on and reinforces stereotypes that are inextricably bound up with socially discriminatory practices and, for reasons similar to those given in §3, can be argued to constitute linguistic discrimination.

Stigmatizing vocabulary, whether used to refer directly to members of stigmatized groups or derivatively to things associated with such groups, exemplifies linguistic discrimination not so much in how the group in question is being distinguished but in how language is being used in reference to them. The clearest examples are derogatory terms applied on the basis of race, gender, sexuality, disability, national origin, religion, and so forth. A related form of linguistic discrimination is the use of terms referring to stigmatized groups as negative characterizations: ’Indian-giver’ or ’Jewing someone down’. Implicitly or explicitly gendered vocabulary typically encodes problematically stereotypical views concerning, for example, the different valuations of male versus female sexuality and assertiveness. Language referring to disabilities is often problematically generalized in ways that imply, for example, that blindness stands in the way of ’seeing’ what follows from a set of premises.

Even when such forms of linguistic discrimination are not blatantly bigoted, there is good reason to avoid them, given the usual desirability of communicating as clearly as possible what is intended to the intended audience. Increasingly, audiences are reading discriminatory intent in the use of discriminatory language (including the supposedly generic masculine), and such reading habits are not in the power of authors to circumvent. To the extent that it is no part of authorial intent either to communicate negative or marginalizing attitudes towards members of particular groups, or to exclude members of such groups (and their allies) from one’s audience, it is wise to eschew vocabulary that will predictably have those effects.

5 Value-laden terminology

Whether or not it is in theory possible for the discriminations made by some particular language (or part of a language) to reflect only morally and politically non-tendentious judgments of similarity and difference, it is clear that such neutrality does not characterize a large number of the distinctions made in the languages we actually use. Public discussions are significantly shaped, in ways that frequently elude explicit debate, by the language in which the issues are framed. A central tenet of moral and political thinking is that like cases ought to be treated alike; consequently the crux of many arguments lies in judgments of similarity and difference, carried out in language that can make some of those judgments nearly automatic and others virtually unthinkable.

Examples abound, from military euphemisms that draw attention towards the achievement of strategic objectives and away from killing people, to abortion debates that pit those who favour choice against those who would coerce child-bearing or those who are pro-life against those who would kill babies. Mainstream press coverage in the USA distinguishes between freedom-fighters and terrorists in ways that map not the activities in which those individuals and groups engage so much as their congruence with or opposition to US foreign policy. Large-scale violence in inner city communities is thought of in one way when called a ’riot’, in another when called an ‘uprising’.

The notion of an ’essentially contested concept’ (Gallie 1956) raises similar questions. Such concepts are deeply value-laden, carrying strongly positive or negative connotations: ’democracy’ or ’repression’. Disputants typically share a small core of paradigmatic exemplars and differ over which additional examples are relevantly similar. A discriminatory use of an essentially contested concept would be one that applied and withheld the term in ways that are argued to be either undermotivated or motivated in problematic ways.

The point is not that we ought to eschew language that encodes controversial judgments of similarity and difference. Rather, we should be aware of what is encoded in our language and ready to argue for the judgments expressed therein and to challenge those of others with which we disagree. To call a particular use of language discriminatory goes beyond the claim that it implies a disputable judgment: rather, it commits one to arguing for why and how that judgment ought to be disputed.

6 Languages and dialects

The historical development of languages has gone on in tandem with the histories of the formation of nations, the spread of and resistance to colonization and imperialism, the globalization of culture and the influence of nationalist movements, and the development and spread of communication technologies. Language is typically bound up with national identity, often in complex and contradictory ways. For example, movements of African nationalism sometimes embrace the language of the colonizer as the language of national unity, rather than divisively choosing among a number of indigenous languages.

Questions about whether something is a language, rather than a dialect, or a dialect, rather than a degraded use of language, will always raise contentious issues concerning present usage and users, as well as about their histories. Charges of discrimination will be appropriate when such judgments appear to be ethnocentric or otherwise biased, as, for example, in the controversy over whether American Black English is a legitimate dialect. The argument that it is rests on pointing out the rule-governed nature of its syntactic, semantic and phonological differences from Standard English, and on the history of its development from the interaction of West African languages with English (Smitherman 1977).

Languages and dialects are attached to particular groups of people, who are related to other groups in frequently hierarchical ways, and those hierarchies are reflected in the ways in which the languages and dialects are thought of and treated. Attempts are sometimes made to maintain the ’purity’ of a language by codifying a version of it that carries both historical and present day prestige. Educational systems typically single out certain dialects as ’standard’ or ’received’: as the paradigmatic exemplars of the language they tend to be regarded not as dialects, but as the language itself, unmarked. Similarly, some speech patterns count as ’accents’, and different accents lead to different stereotypical ascriptions of intelligence and social standing.

Reflecting the dominance of the USA following the Second World War, English is increasingly the global language - used, for example, in commerce, electronic communications, aviation and science - a development that privileges those who speak it fluently and marginalizes or threatens the survival of other languages. To regard the globalization of English as discriminatory is to regard that situation as other than natural, inevitable or equitably beneficial. Discrimination is also an issue when it comes to the semantic, syntactic and phonological diversity of English as spoken in different countries. Britain and the USA each have large amounts of rather different sorts of clout when it comes to determining whether or not something counts as ’proper’ English, while even native English speakers from elsewhere are generally regarded as speaking either incorrectly or in a substandard dialect.

Linji (810/15-67)

Linji was one of the most reputed, and influential Chinese Chan masters in the history of East Asian Buddhism. He belonged to a school which advocates sudden enlightenment without dependence on words: there is an extralinguistic reality that can be intuitively apprehended through the rigorous meditative training. A person with this intuition escapes dualistic thinking and has grasped the freedom to act decisively, utilizing creatively whatever is presented before him/her. Linji's method of teaching is often characterized as 'thundering shouts and showering sticks', actions which are used to effect an awakening in his disciples. His reputation rests primarily on his ability to seize on this opportunity.

Linji Yixuan, a native of Nanhua county, became a monk at an early age, and studied *vinaya*, the *sūtras* and their commentaries extensively. Unable to gain peace of mind through textual studies, however, he changed to Chan (in Japanese, Zen) Buddhism under the tutelage of Huangbo (?-850). The *Linjilu* describes his dedication to Chan meditation as pure and single-minded. He attained great enlightenment through the assistance of both Huangbo and Dayu, prior to which event he said he was 'totally in the dark'. After twenty years with Huangbo, Linji moved in 849-50 to a temple in Zhengding county of Hebei province, where he taught his disciples for some ten years until his death at the Xinghua Temple. Posthumously, he was given the title 'Chan Master of Illuminating Wisdom'. The *Linjilu*, a record of his sermons, critical examinations and a biography, was compiled in 1120 by Yuanjue Zongyan.

Linji's philosophy focuses on the affirmation of the 'here and now' in the everyday world by bringing at a stroke the transcendental world (that is, the world of *buddhas* and patriarchs) into this world by collapsing the distinction between them. For example, we find in the *Linjilu* that 'there is a true person of no rank in a red chunk of your flesh, and it always comes and goes out of your face'. The 'true person of no rank' refers to the transparent light which, though invisible to ordinary eyes, shines forth in one's daily activities ('your face'). Because the light permeates the person as they originally are, the person lacks nothing, and in order to be emancipated from the sufferings and struggles encountered while living in the world and beyond, all one has to do is to come to this awakening. However, this awakening is paradoxical in that 'if you try to seek it, it retreats into the distance, and if you don't seek it, it appears before your eyes'.

The paradox arises, Linji observed, because the ordinary person suffers from a 'dis-ease' in the pursuit of the Buddha Way. He attributed the cause mainly to the lack of self-confidence. Doubts created in the mind cause the mind to fluctuate, chasing thoughts or images one after another: the fluctuating mind operates on the basis of dependence on people, language and things, through which the mind enters a conditioning process of transformation with the external world. Unable to discern this transformational process and mistaking it to be real, the ordinary person accepts the phenomena thus presented. For Linji, however, these are simply metamorphosing illusions and delusions, and are 'self-binding without any rope'. True reality discloses itself in a clear illumination beyond any dependence upon people, language and things.

Linji's cure for the 'dis-ease' was to discover the mind that does not fluctuate by achieving the stillness of meditation, and thereby to disengage it from the dependent, conditioning process of transformation so that the mind becomes immovable. He called it the one (unified and unifying) mind. If the mind is immovable, it becomes nondependent. It may be pointed out that the mind of dependence objectifies the things of experience and substantializes them through its discursive and discriminatory activity. This renders the mind incapable of letting things disclose themselves in total transparency because it creates the distinction between the appearance of a thing, and its nature. By contrast, the nondependent mind performs none of these activities, for it does not engage an object by discriminating and objectifying it.

Linji's position of nondependent mind leads to the thesis that anything existent lacks a substantial nature that persists through time. Everything is empty of substance, including the mind which experiences its world. In the experience of emptiness where all *dharmas* are experienced as one in the transparency of pure light, the person realizes that nothing whatsoever is obtainable, even the goal of becoming a *buddha*, for if everything is empty, nothing can be obtained. The mind which realizes this is without form, that is, 'no-mind', in virtue of which its activity is capable of penetrating the whole world (see Buddhist concept of emptiness).

In summary, the nondependent mind frees the person from the adverse, delusory influences of the everyday world, for the conditioning process is incapable of affecting the immovable, no-mind. The person with nondependent mind is also free from the karmic destiny of birth and death, because the experience of emancipation *vis-à-vis* the emptiness of things unties the person from his/her self-binding (see Karma and rebirth, Indian conceptions of). Moreover, based on this realization, the action performed by the person of nondependence does not leave any karmic residue, and therefore the freedom from karmic determination enables the person to freely engage, by way of verbal or bodily behaviour, the matters of the triple world - the experiential worlds of desire, form and formlessness. Freedom for Linji is grounded in the power of discerning 'the *buddha* from the devil, the true from the false, and the sacred from the profane'. Linji encapsulated the characteristics of the person of nondependence in his statement: 'If one becomes a master in any place, wherever he stands is true'. He called such a person the 'person of no-event'. He exhorted people to make use of the nondependent, immovable no-mind by embodying it.

Linnaeus, Carl von (1707-78)

Linnaeus was educated in Sweden, and became a doctor of medicine in Harderwijk, Holland, in 1735. He visited other European countries then, but he never left Sweden after his return in 1738. After practising as a physician in Stockholm, he moved to Uppsala University as professor of medicine and botany in 1741. He articulated four different but complementary ways of understanding nature - through two kinds of classification, and through what can be called developmental and functional/ecological interactions. Linnaeus is best known for his classificatory work, for which he received material from all over the world. His classificatory precepts are elaborated in the Philosophia botanica of 1751, an enlarged version of the 365 aphorisms of his Fundamenta botanica of 1735; the other aspects of his work are diffused through his writings. His artificial classification system, initially very popular, was replaced by the 'natural' system, more slowly in botany than in zoology, and more slowly in England than in some other countries. Current biological nomenclature is based on his Species plantarum, edition 1 (for plants), and Systema naturae, edition 10 (for animals). His codification of botanical terms remains influential. Almost 200 dissertations, most written by Linnaeus, were defended by his students. In these and other less well-known works, including the unpublished Nemesis divina (Stories of Divine Retribution), he covered a wide range of subjects. Quinarian thinking is noticeable in Linnaeus' work - there are five ranks in systems, five years' growth in flowers - and in some of the occult works that he knew. He also shows a strong combinatorial bent and a tendency to draw close analogies between the parts of animals and plants.

1 Formal classification

Linnaeus was educated at Lund and Uppsala universities (he was originally destined for the priesthood); his field knowledge was largely restricted to Sweden. During Linnaeus' three years in Holland, mostly in the employ of the wealthy banker George Clifford, he published extensively, including the first editions of *Systema naturae* and *Genera plantarum*. Later, his work mostly represents elaborations of his early ideas.

Linnaeus defined natural history as the classification and naming of plants, animals (including humans) and minerals according to the number, shape, position and proportion of their parts. Classification (*dipositio*) was based on system, Ariadne's thread, and was applicable to all branches of knowledge. There were five ranks, class, order, genus, species and variety, members of each rank (except the last) including several members of the subordinate rank. Successive divisions were based as far as possible on essences, 'lubricious' distinctions, such as those between herb and tree, being avoided. Classes and orders in the sexual system of plants ('such loathsome harlotry', according to Johann Siegesbeck) were distinguished by stamen number, whether or not the stamens were joined together, and their position relative to the pistil; they were the work of nature and art.

Genera and species were the work of nature. Genera, the focus of Linnaeus' work, were defined by features of the fructification (flower and fruit), largely those of external form. Linnaeus calculated that the different parts of the fructification, when combined in all possible ways, would yield sufficient features to distinguish all plant genera. These features were often taken from Linnaeus' examination of one species per genus. Other species were added because of their agreement in *habitus*, features other than those of the fructification. Hence Linnaeus' species of *Vaccinium* (cranberries, blueberries), although similar in appearance, had different numbers of stamens in the flower - and so should have been placed in different classes. Linnaeus' contemporaries were dismayed by such inconsistencies; Linnaeus was not.

Species were the basic unit of nature, and he first thought they were all created. They were distinguished by differences in the number, shape, proportion and position of parts like the stem, leaf and inflorescence, but not by odour, length of life, and so on. Varieties, variation produced by sowing the seed of one individual, were often the result of cultivation and were rarely of importance.

The idea of 'character' anchors the system. The essential character was the essence of a genus in a natural system, while the factitious character defined the genus in an artificial system. Both were based on features of the fructification and, when combined, made a natural character. The description was the natural character of the whole plant, so it included the habitus. For species, natural characters were descriptions, essential characters were differentiae. Finally, a *naturalissima* character contained features common to many plants.

The correct naming (*denominatio*) of plants was critical. The name of a genus was a single word ideally reflecting either its habitus or an essential feature, and Linnaeus proposed extensive guidelines for naming, relegating unacceptable names to synonymy. The specific name was a polynomial, the essential character of the species. A mere twelve words could provide differentiae for all species in a genus of 100 species when the differentiae were qualified by adjectives and used synoptically (that is, dividing the genus successively in half: 50, 25, 13, 7, 3, 2, 1). Since essential characters were not known a priori, as new species were added to a genus the polynomials (differentiae) of the other species might have to be changed. Moreover, when a species was moved from one genus to another, its name would change if the differentiae in the new genus differed. Names were not linked to specimens, all individuals of a species sharing the same essence; Linnaeus treated specimens as being by and large interchangeable.

The trivial name was a single, usually adjectival, word which, with the generic noun, formed the binomial. (Linnaeus abbreviated book titles in a comparable fashion, and binomials were initially provided for convenience.) Few nomenclatural rules applied to trivial names, which did not reflect the essence, but their value was such that they pervaded biological literature after 1753 and are often described as ‘Linnaean names’. Linnaeus’ reform of genera and species and his nomenclature were widely influential.

2 The natural method

The natural method was ’the ultimate goal of botanists’. There genera were grouped into orders; these were named, but not described (exceptions are the early *Musa Cliffortiana* and Paul Dietrich Giseke’s descriptions in the *Praelectiones* of 1792, presumably those given by Linnaeus in lectures in 1771, but never published). Linnaeus realized that natural orders could not be defined. Even the most ’natural’, such as the *Umbelliferae*, the carrot family, lacked features that were unique to and constant within them. Until these were found, natural groups were ’like a bell without a clapper’; in modern parlance, they were polythetic.

Plants showed relationships on all sides, like territories on a map. (The diagram of relationships drawn by Giseke showed ’genealogical-geographical affinities’; too much emphasis should not be placed on the genealogical element, since trees of knowledge were described in similar terms.) However, plants still undiscovered caused problems in establishing both relationships and groups. When discussing such problems, Linnaeus made the oft-quoted statement, *natura non facit saltus* (nature does not make leaps); continuity made definition difficult. Thus although there is no simple *scala naturae* in Linnaeus’ work, relationships form a continuum. Characters do not define groups, indeed, in the chain of variation there is no real discontinuity even between animals and plants: plants have flowers, as do animals - but only those animals like *Hydra*, with its corolla-like circlet of tentacles, immediately adjacent to plants in the series. Such continuity pervades Linnaeus’ work, *Homo troglodytes*, which linked *Homo sapiens* to other animals, being another striking example.

3 Developmental interactions

Interactions between two basic tissues, the cortex and medulla, explain the development of organs, the relationship between the inside and the outside of organisms, why different characters were used at different levels of the systematic hierarchy, the general nature of organic diversity, and even ideas of disease and its cure. Organisms were made up of cortex (the male principle; responsible for form) and medulla (female; life). Form was manifest in the cortex only after a basically epigenetic interaction with the medulla. In most animals, determinate in growth, the cortex enclosed the medulla, while in most plants the medulla pushed through the cortex and growth was indeterminate; both plants and animals had definite form. Fungi, however, had only a thin layer of cortex, so their form was notably labile and their classification, which depended on constant form, consequently chaotic. Finally, in organisms like the genus *Chaos* (amoeba) itself there was neither cortex nor constant form. Linnaeus toyed with the idea of establishing a separate kingdom for such organisms.

The vegetative organs of the plant, and most of the fructification, were cortical in origin. Each organ was formed from a particular subtype of cortical tissue, thus stamens represented the innermost part of the cortex (lignum, or wood); the pistil, however, was almost pure medulla. Fertilization thus brought together male (cortical) and female (medullary) elements. If for any reason the medulla died or was used up, the plant itself died; thus in annual plants all the ’growing points’ of the medulla entered the ovaries, none remaining to continue growth.

Linnaeus equated flowering in plants with metamorphosis in insects. The young stages of the organism, the outside parts, were discarded, and the adult (insect, flower), representing the insides, emerged. Hence the different parts of the plant fructification were equated with elytra (wings) and genitalia, and the butterfly with 'a flying flower'. Metamorphosis confirmed Linnaeus' use of characters of the fructification in defining genera; they were characters of the adult. Vegetative characters, external and juvenile, were useful only as specific differentiae. (He also discussed the relationship between the animal and plant kingdoms as a form of metamorphosis in which cortex was sloughed off.)

The cortex-medulla theory had numerous implications. Linnaeus drew a parallel between the growth of the vegetative bud and that of the flower: the flower, with its five main organs, representing the equivalent of five years' vegetative growth in one. Moreover, by incorporating ideas of plant nutrition, curiosities such as flowers with only a single covering that was green on the outside and coloured on the inside, and the association of doubled flowers with varying degrees of sterility, could be explained. From observations of such phenomena, including *terata* (monstrosities), Linnaeus concluded that plant structures were interconvertible - independently of and prior to similar ideas expressed by Goethe (see Goethe, J.W. von §3). Leaves could change into sepals, sepals into petals, and petals into stamens. (Note that most observations Linnaeus used here were valueless for his classification; doubled flowers were at most varieties.)

Finally, the cortex-medulla theory is integral to ideas Linnaeus developed on the generation of organic diversity. His species concept - that all species were created by God - was soon amended. Hybridization, he thought, produced the new genus *Peloria* (in fact, a mutant of toadflax) and also occurred between other genera (in combinations that are patently impossible), yet it would not destroy the overall taxonomic framework. Since the cortex of the male determined vegetative form and hence the specific character, and the medulla of the female effectively determined features of the fructification and hence the generic character, hybrids were simply new species in established genera. Thus hybridization could account for variation in taxonomically difficult genera like *Rosa*. Later, Linnaeus came to think that God had created a small number of cortex-medulla combinations representing orders or even the three main groupings of plants (based on cotyledon number). Successive hybridizations then yielded the diversity of form as manifest in the classificatory hierarchy.

4 Functional/ecological relationships

Linnaeus held physico-theological ideas of balance and compensation in nature, with a series of controls, dependencies and connections existing within and between organisms. Bird colours were important in courtship; the flowers, fruits and leaves of plants were arranged to facilitate pollination and seed dispersal. Most insect larvae ate one species of plant, and often one part of that plant; some ate other insects; plant galls housed yet other larvae. Water in the pitchers of *Tillandsia* was for the use of thirsty humans, birds and beasts alike; evergreen trees grew in barren places to provide shelter for animals in winter. Food chains, from the minute *Monoculus* to gnat to frog to pike to seal, and ecological successions, from crustaceous lichens on a rock by the sea to foliose lichens to mosses to herbs and shrubs, formed other connections, as did geomorphological changes.

Ultimately, reproduction had to be checked, since simple calculation showed that otherwise single species would come to dominate nature. Hence small and useful, that is, edible, animals reproduced more than large and useless animals. After caterpillar larvae devastated grasslands, more plant species could grow there. Death and life were inseparably connected; nature was in balance.

Organisms were for human use, too, although in general Linnaeus did not think that some organisms existed for the simple and unrestricted use of others. However, he argued that the study of natural history allowed humans to use natural productions more effectively (his strong cameralist inclinations are relevant here), and about one in six of Linnaeus' theses deal with this theme. The final link in the theodicy was the *Nemesis divina*; God kept humans in check.

5 Conclusions

Linnaeus' ideas owe much to those of Cesalpino, and ultimately to Aristotelian thought. Logical division yields natural groupings only in a taxonomy of analysed entities, and Linnaeus realized that he did not have such knowledge of animals and plants; his claims for the results of the a priori reasoning he applied were modest.

Stamens, although important in reproduction, were not a true *fundamentum divisionis*, hence classes and orders were the work of nature and art and were only partly natural. Indeed, Aristotle had argued that logical division was an inappropriate tool for the classification of organized beings. It is difficult to relate Linnaeus' ideas of development directly to those of Aristotle, in which the male is usually the active element, shaping a passive female substance. However, Aristotle's general teleological framework bears comparison with that of Linnaeus (see Aristotle §17).

Linnaeus came to believe that species were the work of time; they were not simultaneously created - although by God's combinatorial, they were foreordained. Such developments of his ideas - let alone his interest in the origin of form and the functional interconnections within and between organisms - escaped many of his contemporaries and successors, and he came to exemplify essentialism, stasis and classification.

Lipsius, Justus (1547-1606)

Justus Lipsius was a Flemish humanist and classical philologist whose work on Tacitus and Seneca led him to give the first full, formal account of Stoicism as a philosophical system, and also to #develop Neostoicism, an influential political and moral theory. His most popular book was De constantia (On Constancy), an account of how to maintain steadfastness in the face of public evils. He loved gardens and dogs.

Justus Lipsius (Joest Lips) was born near Brussels, and lived through the Protestant revolt against Spanish Catholic rule over the Netherlands. Lipsius came from a Catholic family, and attended the Jesuit college at Cologne before going to the University of Louvain. Here he studied law, but soon turned to classical philology (though he never perfected his Greek). His first published work, *Variarum lectionum libri IV (Four Books of Mixed Readings)* (1569), was dedicated to Cardinal Granvelle, who appointed him Secretary for Latin Letters. Granvelle introduced Lipsius to scholarly circles in Rome, where he spent the years 1568-70. In 1571 he went to Vienna, and then to Jena, where he held the chair of rhetoric and history from 1572 to 1574. To hold this chair, he had to profess Lutheranism. On leaving Jena in 1574, he went to Cologne, where he married a Catholic wife, then to Louvain, where he completed his law degree in 1576. Fearing difficulties with the Spanish authorities, he next went to Leiden where he was professor of history from 1579 to 1590. Here, he had to profess Calvinism. In 1591 he made his peace with the Jesuits at Mainz and returned to the Spanish Netherlands. In 1592 he was appointed to the chair of history and Latin literature at Louvain, a post he still held at his death. He was also named historiographer to the King of Spain in 1595. Lipsius, along with his dog Mopsus, appears in a famous painting, *The Four Philosophers,* by Peter Paul Rubens, whose brother had been a pupil of Lipsius at Louvain.

Lipsius' first notable achievement was the edition (1574) of the Roman historian Tacitus, whose works had been rediscovered in the late fourteenth and fifteenth centuries. Lipsius was among those thinkers who interpreted Tacitus as counselling political prudence and non-involvement in affairs of state. In 1589, Lipsius published his own work on politics, *Politicorum sive Civilis Doctrinae libri sex (Six Books of Politics or Civil Doctrine)*. His treatment of military affairs stimulated Dutch army reforms, but the chief importance of the work lay in Lipsius' appeal to the political and moral values of Ancient Rome, and his acceptance of the central role of the state. The importance that Lipsius attached to political stability led him to advocate the enforcement of a state religion, but in the first edition he also counselled toleration of private belief. As a result, his work was placed on the Index.

Lipsius' advocacy of Neostoicism in political theory was supplemented by his Neostoicism in ethics and his work on Stoicism as a philosophical system. In his very popular book *De constantia (On Constancy)*, first published in 1584, and republished many times, both in Latin and in translation, Lipsius discussed the individual's attitude towards public troubles, advocating steadfastness guided by reason, freedom from the emotions, patience in adversity, and cheerful subjection to God. He recognized that Stoicism had to be modified for, contrary to Stoic views, God is not subject to destiny, but rather destiny is subject to God. Divine providence is not an impersonal fate, and it can be reconciled with both chance and human free choice.

In 1604 Lipsius published two books on Stoic doctrine in which he argued that Stoicism, while not wholly acceptable, was the philosophy best suited to Christianity. The first, *Manuductio ad Stoicam philosophiam*, is a handbook dealing with ethical questions, including friendship and suicide (which Lipsius was against), and with the sources for Stoicism. The second (*Physiologia stoicorum*) is a study of Stoic physics as providing an essential foundation for the study of Stoic ethics, given the injunction to lead one's life in accordance with nature. Lipsius was more positive about the compatibility of Stoic views on fate with Christian views about divine providence than he had been in *On Constancy*. He also took up Stoic views on God as a divine fire infused throughout nature, on eternal matter, and on soul as material. The book presents the first systematic modern account of Stoicism (see Stoicism).

Lipsius' last contribution to the knowledge of Stoicism was his 1605 edition of Seneca's *Opera omnia* which includes an unfinished commentary and essays. Seneca had always been important to Lipsius, not just as a thinker but as a stylistic model.

In a letter of 1603, Lipsius summed up his work in these words: 'I was the first, or the only one, of my time to turn

my scholarship to Wisdom; out of Philology I made Philosophy' (Morford: 137).

Literature, Japanese philosophy in modern

Since the last quarter of the nineteenth century, virtually all major lines of Western thought and the works of both major and minor Western philosophers have been explored and used by Japanese writers in an effort to forge a modern Japanese literature. The history of translation alone reveals a concern to bring over synoptic summaries of Western philosophy, as well as the primary works of specific thinkers. Academic philosophy as a discipline of advanced study was established in the 1880s, the decade which corresponds to the beginnings of widespread literary reform and the often-cited creation of the first modern Japanese novel, Futabatei's Ukigumo (Floating Cloud) in 1889.

However, Japanese novelists, dramatists, poets and critics did not assimilate philosophical influences naïvely or passively, nor was Japanese literature made over in the shape of specific Western ideas regarding the nature and function of the self, society or literary aesthetics. Indeed, the avid translation and discussion of Western ideas frequently provoked a nativist reaction or modification. The revival of traditional tropes, the language of Confucian ethics, Buddhist practice and Shintō legends), itself often reflects the pervasive presence of Western ideas on the modern literary scene.

1 Modern literature

Few Japanese literati since the Meiji period (1868-1912) have been philosophers in an academic sense. It can be difficult to isolate specific Cartesian, Kantian, Bergsonian or Heideggerian elements in a work allegedly written under their influence. As Japanese literary critics themselves have pointed out, time and again writers responded less to an idea as such than to particular imagery, or even to the biography or the historical predicament of certain thinkers. This is especially true where Modern, Enlightenment and post-Enlightenment philosophers are concerned, that is, cultural figures who were struggling to fathom intellectual, historical and social problems analogous to those confronting Japanese writers in the late nineteenth and twentieth centuries.

The beginnings of modern literature in Japan are usually traced to the 1880s, when the literary critic Tsubouchi Shōyōand the novelist Futabatei Shimei gave voice to a new style of realism and pioneered a literary language that placed greater emphasis on speech and the expression of ordinary life. Their efforts reflect a conception of literature shaped by Western modes of literary realism (in Futabatei's case, by his study of Russian and his translations of Turgenev) and by their awareness of the ascendancy of the realist novel on the Western scale of literary values. This shift in emphasis, from literature traditionally viewed in Japan as a rhetorical medium for lyrical expression to that of a transparent reflector of things as they are, paralleled shifts and reforms being undertaken in Japanese politics, law and education. Most such reforms occurred within the prevailing atmosphere of utilitarian, Enlightenment and social Darwinist thought, as it was understood through the writings of John Stuart Mill, August Comte, Jean-Jacques Rousseau, Herbert Spencer and others.

This mid-Meiji reform of literature, making way for a realism that would transcribe modern life as it is, met with a strong idealist reaction, itself mediated by a knowledge of similar counter-Enlightenment tendencies in Western (especially German) thought and writing. Hegel and Eduard von Hartmann were known to Mori Ōgai, who had studied in Germany and based his earliest writings on that foreign experience. Contrary to the brand of literary realism propounded by Shōyō, Ōgai argued that literature exists in a world of ideas and ideals apart from the everyday, where writers and works of genius from anywhere in the world exist on an equal, if lofty, plane. Whether realist or idealist, these mid-Meiji reformulations of literature were calculated to raise Japanese literature to the perceived level of superiority achieved by Western writers. They also reflect a general anxiety over Japan's vulnerability *vis-à-vis* the West and ultimately, over Japanese identity in the modern world.

2 The self

By the turn of the century, when a confessional strain of 'I-novel' writing took shape as the dominant genre of modern Japanese literature - a dominance that prevails to our own day - Christianity as a system of Western thought found its way into literary expression. Anti-institutional, introspective, Calvinist and Quaker-inflected brands of Protestantism, most clearly exemplified in the life and work of the Christian convert and educator Uchimura Kanzo and his 'no-Church' movement, both justified and provided a rich vocabulary for the literary

emphasis on love and the self. Training at Christian mission schools, a conversion experience or some significant exposure to Christianity, was shared by many of the most significant Japanese writers of the twentieth century, including Kitamura Tōkoku, Tayama Katai, Shimazaki Tōson, Kunikida Doppo, Masamune Hakuchō, Shiga Naoya and Arishima Takeo. Apostasy often followed a declaration of faith, which only deepened the need to confess, or the theme of betrayal, within the genre of the I-novel.

The ‘discovery’ of this interior self, necessitated by Christianity, has been described in Japanese criticism as either a symptom of, or a solution to, several modern problems. The self has been seen to serve a variety of cultural purposes: to fill the void left by the collapse of an orderly, neo-Confucian world view, to have satisfied psychological demands made of writers within a rapidly modernizing nation-state, and to have provided a system of ‘transcendent’ values to rival the predominant stress on immanence within the traditional modes of Japanese thought, Confucianism, Buddhism and Shintoism. Still, in specific works of literature, the emphasis on the self or on the value of romantic love often gives way to its loss or rejection. For example, in Shiga Naoya’s famous *Anya Korō(A Dark Night’s Passing)*, the afflictions of self-consciousness yield to a new found sense of harmony within nature and the dissolution of the self within a comforting, spirit-filled landscape.

The literary expression of personal experience was further reinforced by prevailing trends in academic philosophy. Neo-Kantian thought, as well as the pragmatism of William James, was especially dominant in the Taishōperiod (1912-25), serving as a spur to Nishida Kitarō, Japan’s first and perhaps greatest modern philosopher. Nishida’s stress on ‘pure experience’ at once represents a reflection of Western idealist ethics and consciousness of self, joined to an Eastern sense of meditation praxis, as in Zen Buddhism. This conjunction of foreign and native ideas is a widely observed characteristic of the literature of this period, as seen in the eclectic use of both Western and Asian imagery in the fiction of Nagai Kafūand Tanizaki Jun’ichirō. Both exhibit traces of Western decadence, which leads to their discovery of the exotic in old Japan or in tales of the disappearance and partial recovery of tradition. This tendency was further exhibited in the work of Watsuji Tetsurō and Kuki Shūzō, influential cultural critics in the 1920s and 1930s. Close familiarity with German phenomenology in the work of Husserl and especially Heidegger led them to explore the distinctive climate or structure of Japanese culture.

The prevailing emphasis in modern Japanese literature on expressions of self, wherein general questions of social structure or cultural identity were engaged subjectively if at all, did not go unchallenged. The great critic of the time, Kobayashi Hideo, focused on the peculiar narrowness of the Japanese I-novel and of modern writers held in sway by a welter of Western ideas and influences. To recover both greater breadth and a sense of cultural balance, Kobayashi argued for the creation of fiction whose protagonists were bound to a recognizable history and society.

3 Marxism

Marxism had considerable influence on Japanese scholarship, education and literature, and dominated literary and cultural criticism in the late 1920s, giving rise to proletarian realism and to social problem plays in the ‘new theatre’ movement. Notable Marxist critics include Miyamoto Kenji, whose essay ‘Haiboku no bungaku’ (Literature of Defeat) in 1929 represented a sharp if ultimately sympathetic critique of the subjectivist fiction and suicide of Akutagawa Ryūnosuke, and Nakano Shigeharu, whose practice as a socially conscious poet and critic spanned several decades including the crisis of recantation or *tenkō*, the phenomenon of ideological reversal that was so conspicuous a feature of Japanese intellectual life in the 1930s. Socialist realism in fiction was practised by Kobayashi Takiji, who became a martyr to the proletarian cause when he was killed in prison in 1933. Nevertheless, at this time, as well as in the immediate postwar years and later amid the political turmoil of the 1960s, Marxism offered Japanese writers both a way to criticize modernity, and a coherent account of the interconnectedness of individuals and groups within society. Confucianism had formerly provided such an account, though with an emphasis on stability and continuity that seemed increasingly remote from a modern world of unceasing change (see Confucian philosophy, Japanese).

Amid the growing forces of nationalism and militarism in the 1930s and the state of total war in the 1940s, many Marxist ideologues either fell silent or subtly exchanged their leftist critique of the West and of modernity for a rightist critique of Western cultural imperialism. A renewed emphasis on the cultural differences between Japan and the West, ironically mediated by a conscious use of German romantic thought from Herder and Schiller through to Heidegger, led to a revival of things Japanese at this time, and to the literary nationalism of such critics as Yasuda Yojūrōand Hayashi Fusao, and of the poets ItōShizuo and Hagiwara Sakutarō. Their tone of lament, and

their imagery of homelessness, wandering and loss, was balanced by their advocacy of Japanese tradition. In poems or impressionistic essays, they sketched provincial journeys and encounters with simple folk as they made their ‘return’ to the country and home, Japan.

4 Postwar period

After the Second World War, during the early period of American occupation, the intellectual atmosphere was marked by the re-emergence of suppressed or apostate Marxists, and by the philosophy of existentialism (see Existentialism). Occupation censors took over from war-time military censors, and writers sought to account for their loss of personal autonomy and authentic experience, as well as for the zero-degree environment of incinerated cities and a society in confusion and collapse. This atmosphere of Sartrean nausea surrounded several leading postwar Japanese authors, contributing to the desert and labyrinth allegories of Kobo Abe, the descriptions of war and moral atrocity in Ōoka Shohei, the tales of deformed historical consciousness in Ōe Kenzaburō, the wasteland poetry of Tamura Ryūichi, the experimental mythology and apocalyptic tone of the dramatists Kinnoshita Junji, Terayama Shūji and Kara Jurō, and the literary criticism of EtōJun and Yoshimoto Takaaki. These authors were concerned, for different political motives, with issues of false consciousness, bad faith and, in the 1960s, agendas for cultural and social reform. They looked for greater freedom from the influence of Western, especially American, culture.

From the 1970s through to the mid-1990s, Japanese literature registered the changes and rifts that marked Western thought over this same period, actively contributing to that critique, uncovering yet again pockets of Japanese or Asian ‘difference’ from the West, and highlighting characteristics that identify contemporary Japan as a model of post-modernity. Continental philosophy and cultural critique, with renewed attention to the Frankfurt school (see Frankfurt School), has been widely translated and discussed in literary journals. So too have Jacques Derrida and Michel Foucault, severe critics of western metaphysics and institutional structures, whose ideas have been used to frame analogous interrogations of Japanese phonocentrism and of Japan’s own coercive social structures. Some see the underlying critique of language and of meaning within post-structuralism as sharing insights with Buddhist or Daoist thought. It has also been argued that deconstruction, for example, is everywhere on display in the Japanese literary tendency toward indeterminate structures, such as elliptical verse, open-ended narratives and non-linear, polysemic theatre (see Deconstruction). There is a sense that these recent turns in Western thought, directed as they are against stable notions of the self and of linguistic and literary meaning, are oddly congruent with the most traditional assumptions behind Japanese literary practice. In this way, critics such as Karatani Kōjin and Asada Akira have sought to situate writing in Japan within a universal crisis of meaning, while taking account of the historical pressures that have provoked both this general crisis and its inflection in Japan.

Finally, it should be said that modern Japanese literature, preoccupied as it has been with the representation of the real or the expression of the personal, reveals too an anxiety that the real may be a tissue of ideas and ideologies, and that the personal may be an illusion in an environment of incessant makeover and change. Beyond any specific influence, this may be the main legacy of Western thought to modern Japanese writing: a quickened sense for the difference between material reality and our ideas about it, as well as for the power of ideas to cross local boundaries and to define human experience in universal terms.

Literature, philosophy in Latin American

Within the Latin American intellectual community, the relationship between philosophy and literature constitutes one of the most interesting chapters in its development. Much Latin American literature is characterized by profound philosophical concerns, focusing on the question of identity. From the time of the conquest and colonization of the American continent in the 1500s, a debate regarding the humanity of the recently discovered inhabitants began in Spain. This debate would prove to be one of the most revealing controversies of sixteenth-century Europe. At the point of colonial expansion, Europe projected a logocentric vision which would incite a unique Latin Americanist philosophical discourse relating to the question of identity.

During the nineteenth century, philosophical discourse was formulated principally through literary expression. At first the quest for a cultural identity was the philosophical focus, although two conflicting positions were evident: the desire to achieve cultural independence from Europe and a yearning for Latin America to become European. This latter position inspired the urge to identify with European culture and from the mid-1900s, with the political and economic success of the USA.

In the twentieth century, from the time of the University Reform of 1918, an academic philosophy emerged close to that of Europe and began to diversify the Latin American philosophical panorama. From the various philosophical stances which arose at that time, one that dominated the cultural arena, despite its occasional relegation to a secondary position in academia, was the urge to articulate a Latin Americanist philosophical discourse which would succeed in transcending its own frontiers through liberation philosophy, beginning in the 1960s.

1 Philosophy as literature

In the philosophical discourses of the colonial and nineteenth-century periods, two trends appear in Latin America: an academic one inspired by the European movements and practised by the Scholastics, such as Alonso de la Vera Cruz (1504-84) and José de Acosta (1540-1600), Scotist Alfonso Bricño (1590-1667), Neoplatonist José Manuel Peramás (1732-93), Enlightenment thinker Eugenio de Santa Cruz y Espejo (1747-95) and positivist Carlos Octavio Bunge (1875-1918). The other Latin Americanist trend articulated its philosophical discourse through literary expression, particularly the essay and the novel. This group of philosophers comprised Mexicans José Joaquín Fernández de Lizardi (1776-1827) and Justo Sierra (1848-1912), Venezuelan-Chilean Andrés Bello (1781-1865), Argentines Juan Bautista Alberdi (1810-84) and Domingo Faustino Sarmiento (1811-88), Chileans José Victorino Lastarria (1817-88) andFrancisco Bilbao (1823-65), Cubans José de la Luz y Caballero (1800-62) and José Martí (1853-95), Ecuadorian Juan Montalvo (1832-89) and Puerto Rican Eugenio María Hostos (1839-1903). Through the literature of this second trend of the nineteenth century emerge the first expressions of Latin American thought.

In 1815 during the fight for political independence from Spain, leader Simón Bolívar (1783-1830) presented the plight of Latin America in the following terms:

> We are neither Indian nor European, but a species midway between the legitimate proprietors of this country and the Spanish usurpers. In short, although Americans by birth we derive our rights from Europe, and we have to assert these rights against the rights of the natives, and at the same time we must defend ourselves against the invaders.
>
> ([1815] 1981: 63-4)

Bolívar only succeeded in defining Latin Americans by decribing what they were not: ‘We are neither Indian nor European’. His Americanism makes reference to his birth only in as much as, culturally, he believed himself to have inherited ‘Our rights from Europe’. It is in this way that the identity plight became a Latin American obsession.

During the 1800s Latin America was viewed by its people as a scene of confrontation between civilization and barbarism. Argentine essayist Domingo Faustino Sarmiento (1811-88) interpreted Latin America’s social conflict as two opposing forces: ‘one civilized, constitutional, European; the other barbaric, arbitrary, American’. Sarmiento felt he was dealing with ‘two distinct societies that were rivals and incompatible’ (1845: 58). The significance of the thought exemplified in the work of Sarmiento is manifested more precisely in novels by such

authors as Ecuadorian Juan León Mera (1832-94). In Mera's *Cumandá o un drama entre salvajes (Cumandá or Drama Among Savages)* (1879) Ecuador's inhabitants separate themselves into two large groups: the foreigners and the natives. The first comprises the 'whites' (of European descent and identified as Christians) and the other group is made up of Indians or Mestizos (of mixed blood). In Mera's work Ecuador does not have a social identity. It is seen as a border of conflict which is defined, in Sarmiento's terms, as the place of confrontation between civilization (European culture) and barbarism (what is perceived as the autochthonous, native culture).

Towards the end of the 1800s the optimism which characterized the intellectuals of independence turned to pessimism. Like the initial liberalism, the conservative positions under the positivist motto *Ordem e Progresso*, or order and progress, also had failed politically, socially and economically. However, among the pessimistic voices of, for example, Bolivian Alcides Arguedas (1879-1946), a group of essayists emerged and looked to the past in order to present a new stance on the concept of identity. Peruvian Manuel González Prada (1848-1918), Uruguayan José Enrique Rodó (1871-1917), Mexican Justo Sierra (1848-1912), Cuban José Martí (1853-95) and Puerto Rican Eugenio María Hostos (1839-1903) are notable figures in the development of this new philosophy. During this period, it was recognized that large sections of the population had been and were being ignored and that, if Latin America was going to save itself, it must save its Indians. In his essay 'Our America' (*c*.1870), Martí declared, 'To know is to resolve. To know one's country and to govern it with that knowledge is the only way of liberating it' (*c*.1870).

2 Philosophy in literature

The independence in 1898 of the last Spanish colonies in America (Cuba, Puerto Rico), the construction of the Panama Canal, the intervention of the USA in the affairs of several Latin American countries and the First World War motivated Latin American philosophers to project their national concerns across the continent. The Latin Americanist philosophers emerged with the intention of reflecting on the problem of identity on a continental scale. Counted among these were Colombian Baldomero Sanín Cano (1861-1957), Argentines Alejandro Korn (1860-1936) and Francisco Romero (1891-1962), Uruguayan Carlos Vaz Ferreira (1873-1958), Mexicans Antonio Caso (1883-1946) andSamuel Ramos (1897-1959), Bolivian Guillermo Francovich (1901-90) and Peruvian José Carlos Mariátegui (1895-1930). The University Reform initiated in Argentina in 1918 extended rapidly throughout Latin America and gave rise to the development of an academic philosophy. From the beginning of the 1930s these philosophers felt the need to recover the Latin American cultural past as a preliminary step to the formulation of an original philosophy.

In the area of literature the concern was more personal and immediate. The problems which arose from an awareness of one's own circumstances were raised in poetry, theatre, the novel and the essay. Latin American reality was analysed and deconstructed and solutions were proposed. In short, this literature dealt with thoughts which were artistically expressed and parallel with, and sometimes even crossing over into, academic philosophy. However, this literature did not concern itself with contextualizing philosophical discourse. Hence, visions of a possible utopian development in Latin America were expressed by authors such as the Uruguayan Rodó (1871-1917) and Mexican Vasconcelos. In his work Rodó defended the integral personality of the person as well as the concept of select minorities. He criticized what he considered to be the levelling propensity of democracies and the excessive concern for materialism and mercantilism in the USA. He proposed that the Latin American 'spirit' be their objective. Against the degradation levelled at the Mestizo people by the positivists, Vasconcelos recognized the Mestizo essentiality, that is, the interracial and intercultural nature of Latin American people, which he perceived to be the future of humanity. According to Vasconcelos (1925), in Latin America, a fifth race, the cosmic race (a mixed race incorporating the creative power of the other races) would emerge, called to guide the destinies of humankind.

The novel during the period up to the 1950s surpassed the philosophical debates surrounding the concepts of civilization and barbarism which prevailed during the nineteenth century. The works by Mexican Mariano Azuela (1873-1952), Argentine Ricardo Güiraldes (1886-1969) and Venezuelan Rómulo Gallegos (1884-1969) were powerful artistic creations which contributed to a profound philosophical reflection in which the cultural past and the problem of Latin American identity were embraced and deconstructed. Gallegos in *Doña Bárbara* (1929) studied the intuitions of Martí and the vision of Vasconcelos. In this novel the problems of Latin America continued to be defined as a confrontation between civilization and barbarism. Imitation was considered barbarism

as were the imposition of alien laws upon one's own reality and egoism in search of rapid enrichment. For Gallegos, the civilizing force is that which trusts in the potential of national powers and which recognizes racial and cultural miscegenation as the basis of national identity.

The novel, particularly the *indigenista* novel, became an instrument of denunciation concerning the state of the pre-Columbian descendants' population. The indigenous population gradually recognized through its exclusion, one of the basic causes of the economic, social and political underdevelopment in which some of the Latin American countries found themselves. Peruvian César Vallejo (1892-1938) and Ecuadorian Jorge Icaza (1906-78) crudely developed the consequences of a culture of oppression: one which paralysed the internal development of a country, accentuated the weakness of its oligarchy and accepted as natural imperialist impositions from the exterior. Peruvians Ciro Alegría (1909-67) and José María Arguedas (1911-69) sought to recover the excluded populations.

The question of identity continued to be the impetus of philosophical reflection within literature. The work of Argentines Eduardo Mallea (1903-82) and Ezequiel Martínez Estrada (1895-64) contained profound philosophical reflections which had repercussions that transcended national boundaries. In countries such as Mexico, where the identity crisis was precipitated by internal circumstances, authors and philosophers, such as Samuel Ramos (1897-1959), Rodolfo Usigli (1905-79), Octavio Paz (1914-) and Carlos Fuentes (1929-), shared a mutual concern.

3 Contextualization of philosophy in literature

In the early 1950s Latin American philosophers began to formulate original thought. *América como conciencia (America as a Collective Awareness)* (1953) by Mexican Leopoldo Zea, exemplified this initial stage which reached maturity in the 1960s. For the first time Latin American thought broke its own boundaries by means of 'liberation thought'. In the 1960s such thought split into three complementary fields: pedagogy, exemplified by Brazilian Paulo Freire (1921-), theology, demonstrated in the work of Peruvian Gustavo Gutiérrez (1928-) and philosophy, reflected in the work of Leopoldo Zea (1912-). All these thinkers analysed and deconstructed Western modernity. Their works emerged at the same time as the postmodern discourses of central Europe, although contrary to postmodernism, they were formulated in an attempt to attain a new, global utopian view of humanity.

Liberation thought in literature had immediate repercussions. Its theoretical originality and rigour stimulated writers to deconstruct and contextualize philosophical discourse as well as think about its theological, pedagogical and socioeconomic consequences. In terms of artistic expression, in addition to the liberation thought which guided them, Latin American writers and central European postmodern theorists found inspiration in the deconstruction of modernity by Argentinian Jorge Luis Borges (1899-1986) and Colombian Gabriel García Márquez (1928-), or the liberation works of Salvadorean Manlio Argueta (1936-) and Nicaraguan Claribel Alegría (1924-).

The context of economic thought was also formulated in Chile by Brazilians Fernando Henrique Cardoso and Enzo Faletto and analysed and deconstructed by Colombian Manuel Mejía Vallejo. Liberation theology is given some context in works such as *El ocaso de Orión (The Setting of Orion)* (1972) by Bolivian Oscar Uzín Ferández and *La cruz invertida (The Cross Upside Down)* (1970) by Argentine Marcos Aguinis. Aguinis's novel, written at the same time as Gustavo Gutiérrez's seminal work on liberation theology (1971), deals with the theological implications of the concept of the 'new man', providing for the poor and tackling the issue of celibacy, as well as analysing the Eurocentrist discourse of the Catholic church and its power structures. Its content prophesied the Vatican's subsequent confrontation with liberation theologians.

Theorists practising liberation thought did not concern themselves directly with the condition of women in Latin America, however, the deconstruction of oppression and the plan for liberation implicit in the new man concept provoked the creation of powerful femininist movements. These movements saw the struggle for women's liberation as intimately linked to that struggle for the liberation of humankind. A new literary model known as the testimonial narrative grew up at this time, pertaining to works by such authors as Mexican Elena Poniatowska (1933-) and Elizabeth Burgos's discussion of Rigoberta Menchú (1983).

The process of contextualizing liberation thought in literature is exemplified, along with more traditional themes, in the novel *Porqué se fueron las garzas (Why the Herons Left)* (1980) by Ecuadorian Gustavo Alfredo Jácome. Jácome's novel also deconstructs the trends of the so-called intercultural philosophy. This philosophy assumes

intercultural relations can be established through the media of literature and philosophy to create a dialogue among equals.The author breaks with the traditional indigenous novel by presenting an Indian with a doctoral education as rector of a school. Jácome goes beyond the search for identity by showing that it is more likely obtained when issues of racial and cultural discrimination are not constantly under examination. The protagonist creatively transcends the oppression that is assumed when one's discourse is expressed in a European language (Spanish). The novel exposes the concealed oppression that carries with it the aspiration in the 1990s of establishing an intercultural dialogue. *Porqué se fueron las garzas (Why the Herons Left)* shows that the most recent state of globalization has established an intercultural dialogue which has a hierarchical diagram and a tacit schema of oppression at its base.

Llewellyn, Karl Nickerson (1893-1962)

Karl Llewellyn was philosophically the most original of the 'American Realist' jurists. His line of argument, sometimes misleadingly called 'rule-scepticism', casts doubt on received approaches to the formulation of legal rules and traditional assumptions about the part they play in law. His approach to law is an essentially functionalist one, owing much to philosophical pragmatism.

Llewellyn was an outstanding US legal thinker, innovative both in legal theory and in approach to legal education and practice. He played a major part in drafting the Uniform Commercial Code (UCC) for the USA. He emphasized the need to appreciate the fact-situations of legal cases in their full lawyerly detail, and the need to reflect on them from sociological and anthropological standpoints, rather than simply tackling them in terms of an oversimplifying prescriptivist jurisprudence.

The target of Llewellyn's jurisprudential critique was the tradition of legal study that takes the task to be that of ascertaining, ordering and transcribing a rather abstract body of rules and principles; this he saw as connecting with a model of legal processes that deems them a straightforward application of ascertained rules and principles to fact-situations. These approaches are characteristic of 'legal formalism', which the realists, a turbulent and critical younger generation of US lawyers in the 1920s, took to be the dominant view in law schools and indeed to be something of an official legal ideology in the country at large (see Legal realism §2).

Llewellyn's intellectual mission was to show that the actual practice of the law, especially in common law systems attaching great weight to precedent, cannot be matched to or helpfully explained by the formalist model. Much more goes into constructing a case as a lawyer than adding together a formulaic rule-statement and an abstract statement of the facts of the case. Precedents do not yield simple rules; rather they have to be subjected to painstaking analysis and synthesis, and looked at in groups by judges, advocates and scholars for their several purposes. There are contexts in which it may be helpful to test the results of this process by viewing them as if they were predictions of judicial conduct rather than prescriptions. The point is that a judge's role is to act 'reasonably' about disputes. This by no means licenses disregard for statutes and precedents, but also brings into play more intuitionistic elements described by Llewellyn as 'situation sense', which requires sensitivity to political and economic realities (see Legal reasoning and interpretation §§1-3).

Behind this lies a functionalist stance in the philosophy and sociology of law, well expressed in his 'law-jobs' theory, where he analyses legal roles and legal rules in terms of jobs to be performed in society. With E.A. Hoebel, he applied this theory to anthropological study of the traditional dispute-settlement techniques of the Cheyenne. It underlies all his later work, and yet was never fully developed as a comprehensive philosophy of law, partly because of the great demands on his time taken by first drafting and then (even harder) securing acceptance for the UCC, in which his approach to drafting exemplifies his theory. His last great work, *The Common Law Tradition: Deciding Appeals* (1960), extols what is in effect a self-conscious functionalism in adjudication, the 'grand style' of judging versus the rival 'formal style'. This is an eloquent plea for acknowledgement of the rule of law as a reconciliation between legal certainty, or 'reckonability', and legal adaptiveness to changing social and economic circumstances.

Llull, Ramon (1232-1316)

One of the most extraordinary figures of thirteenth-century Europe, Llull was a self-taught lay theologian and philosopher, chiefly concerned with reforming Christian society and converting unbelievers. Details of his life remain obscure, but over 200 of his writings survive. Most of these expound his personal dialectical system, the Great Universal Art of Finding Truth, an encyclopedic collation of commonplace doctrines that attempts to show how all human knowledge conforms to divine truth. Largely ignored during Llull's lifetime and denounced as heretical in the later Middle Ages, the Great Art became very popular in the Renaissance as a programme of universal knowledge.

1 Career

Ramon Llull came from a prosperous Catalan merchant family that had helped conquer his native Majorca from the Arabs in 1230. Little information exists about his life: several letters document his contacts with civil or ecclesiastical authorities, and his writings include some autobiographical details. Most information comes from a brief *Vita (Life)* composed in 1311 by admirers at Paris. Llull pursued secular affairs (perhaps as a royal official) until about 1263, when visions of Christ moved him to serve God instead. He dedicated himself to three goals: writing a book to refute 'the errors of the infidels', establishing schools to train Christian evangelists in Oriental languages and converting all unbelievers. He spent ten years in private study and contemplation, acquiring a Muslim slave to teach him Arabic and perhaps receiving some formal education from local religious houses. Eventually he conceived the plan for a Great Universal Art of Finding Truth, which he attributed to divine inspiration. Around 1275 Prince James of Majorca summoned Llull to Montpellier so that church authorities could examine his writings. After this he travelled constantly, presenting his plans at the courts of Aragon, France, and the papacy, visiting the University of Paris, attending meetings of religious orders and church councils, and making private missionary trips to North Africa and the Eastern Mediterranean. Llull's greatest success came apparently in 1311 at the Council of Vienne, which created chairs of Oriental languages at several major universities. However, he often complains that his contemporaries ignore him, and depicts himself as a lone 'fool'. Llull wrote some 250 works in Catalan, Latin and Arabic. None of the Arabic works has survived.

2 The Great Universal Art of Finding Truth

Nearly all Llull's writings expound his Great Universal Art of Finding Truth, which broadly constitutes a comprehensive scheme for achieving the ancient Christian ideal that Bonaventure called 'retracing the arts and sciences to theology'. Llull's Art synthesizes the methods of contemplation and missionary argument that he evidently absorbed during his decade of private study. Though often compared to scholastic works such as Aquinas' *Summa theologiae*, Llull's system is in fact more popularizing. He often recommends it as a simpler alternative to the complex university curricula of his day, which he characterizes as abandoning the quest for divine truth in favour of quibbling over human errors. Llull especially criticized the schoolmen of Paris as 'Averroists' (see Averroism). His spiritual and intellectual values were thus basically conservative: he sought to maintain the subordination of philosophy to theology and the primacy of cloister over classroom in Western Christian culture.

Llull's Great Art tries to show how the many truths of human learning all depend on one divine truth. It accomplishes this by tracing the manifestation of certain 'divine dignities' (attributes of the Godhead) in every entity. The mature versions of his system specify nine divine dignities (goodness, greatness, eternity, power, wisdom, will, virtue, truth and glory) as 'absolute principles' of all being and knowledge. Nine more 'relative principles' (difference, concord, contrariety, beginning, middle, end, superiority, equality and inferiority) explain the diffusion and operation of the absolute principles in various 'subjects' of existence (God, angels, heavens, humans, imagination, senses, elements, vegetal power, and skills and arts). Finally, nine 'rules' (whether? what? why? from what? what kind? how much? where? when? and how?) function as heuristic questions for guiding inquiry about the principles and subjects. Llull usually creates lists of other categories necessary for applying the Great Art to particular fields of inquiry.

The most remarkable feature of his system is its use of the letters B, C, D, E, F, G, H, I and K to symbolize each set of nine principles or rules (the letter A is reserved to symbolize the coincidence of all absolute principles in

God). Llull’s handling of these symbolic terms owes little to the propositional or syllogistic structures of Aristotelian logic. Instead, he employs circular or tabular charts (called ‘figures’) to show all possible combinations of two or three letters, in the manner of mathematical multiplication tables. These dual and triple letter combinations are intended to comprehend all possible philosophical and theological propositions. Llull develops the combinations into discursive statements and analyses their ‘truth’ by applying a wide range of analogical, allegorical, proportional and figural arguments. He insists that these arguments constitute ‘necessary reasons’ capable of ‘demonstrating’ the truth of Christian belief. Successfully using the combinatory figures and necessary reasons of Llull’s Great Art depends almost completely on a correct understanding of the meanings assigned to the letters B through K. This understanding in turn invariably requires extensive interpretative work, guided by unswerving fidelity to Christian dogma.

Llull almost never cites any authorities but his own writings and routinely recasts all theological or philosophical questions in the vocabulary of his Great Art. Consequently, the sources for his work remain very difficult to identify. Llull’s pre-eminent concern for evangelizing probably motivated his preference for commonplace doctrines (such as the divine attributes) that would be comprehensible to Christians, Jews and Muslims alike. Some scholars have sought global precedents for Llull’s arguments in a single Hebrew, Latin or Arab authority, such as the *Zohar*, Bonaventure or Algazel (see Al-Ghazali). However, his erudition rarely exceeds the level found in widely-circulated Latin or Arab theological and philosophical compendia.

His combinatory methods and necessary reasons do generate some novel propositions. For example, his metaphysics relies heavily on broadly Neoplatonic principles of the emanation, participation and resemblance of all beings (see Neoplatonism). He advocates the reality of all universals and attributes both matter and form to all things, except God. Yet he does not functionally distinguish substantial from accidental forms, and rarely appeals to Aristotelian concepts of causality. Instead he refers all real or mental relationships to the ‘coessential implication’ of the divine dignities in the Godhead, and ascribes to every being three ‘innate correlatives’ of ‘act’, ‘activity’ and ‘passivity’ as a reflection of the divine Trinity. In psychology, he follows well-known Augustinian, Aristotelian or Avicennan doctrines, but also treats imagination as a separate level in the soul and classifies speech as a sixth sense (because it serves the exalted purpose of comprehending God). In logic, his doctrines largely correspond to the Scholastic ‘old logic’. However, he simplifies sophistics by proposing a ‘master fallacy of equivocation’, arguing that this explains all the other fallacies identified by Aristotle as failures to distinguish the apparent sense from the true sense (that is, the Christian interpretation) of disputed propositions, such as ‘The world is eternal’ (see Eternity of the world, medieval views of). He also recommends a new method of demonstration *per aequiparantiam* that will show ‘coessential’ relationships. In ethics, he extends a concept of moral finality to all beings, insisting that every being possesses the dual ‘intention’ of either serving God or contributing to this service. Ultimately, Llull’s arguments make most sense if regarded as a comprehensive natural theology: his Great Art is arguably the Christian Middle Ages’ most ambitious attempt to explain how all creation manifests its Creator (see Natural theology).

3 Llull’s legacy

In the fourteenth century, Llull’s work came to attract non-academic lay people and clergy who valued its spiritual ideals, although the Aragonese Inquisition challenged their orthodoxy. Nicholas of Cusa was the first of several important thinkers whose interest in Llull made the Great Art widely known in the Renaissance and early modern era. Authorities from Giordano Bruno to Leibniz praised its pansophistic method, and schools of Lullism flourished on Majorca into the eighteenth century. An extensive body of modern non-scholarly literature on Llull exists; only a few of the best critical or historical studies are in English.

Locke, John (1632-1704)

John Locke was the first of the empiricist opponents of Descartes to achieve comparable authority among his European contemporaries. Together with Newton's physics, the philosophy of An Essay concerning Human Understanding gradually eclipsed Cartesianism, decisively redirecting European thought. Neoplatonic innatism was replaced with a modest, naturalistic conception of our cognitive capacities, making careful observation and systematic description the primary task of natural inquiry. Locke saw himself as carrying out just such a descriptive project with respect to the mind itself. Theorizing is the construction of hypotheses on the basis of analogies, not penetration to the essences of things by super-sensory means. In religion Locke took a similarly anti-dogmatic line, advocating toleration and minimal doctrinal requirements, notably in Epistola de tolerantia (A Letter concerning Toleration) and The Reasonableness of Christianity. Through his association with the Earl of Shaftesbury he became involved in government, and then in revolutionary politics against Charles II and James II. The latter involvement led to exile, and to Two Treatises of Government, a rejection of patriarchalism and an argument from first principles for constitutional government in the interests of the governed, and for the right of the misgoverned to rebel. Locke published his main works only after the 'Glorious Revolution' of 1688. He undertook important governmental duties for a time, and continued to write on many topics, including economics and biblical criticism, until his death. The Essay, Epistola and Second Treatise remain centrally canonical texts.

Locke held that all our ideas are either given in experience, or are complex ideas formed from simple ideas so given, but not that all our knowledge is based on experience. He accepted that geometry, for example, is an a priori science, but denied that the ideas which are the objects of geometrical reasoning are innate. 'Experience' includes 'reflection', that is reflexive awareness of our own mental operations, which Cartesians treated as a way of accessing innate ideas, but which Locke calls 'internal sense'. To have ideas before the mind is to be perceiving given or constructed sensory or quasi-sensory images - things as perceived by sense. In abstraction, however, we consider only aspects of what is presented: for example, a geometrical proof may consider only aspects of a drawn figure, allowing generalization to all figures similar in just those respects. Universal knowledge is thus perception of a relation between abstract ideas, but we also have immediate knowledge, in sensation, that particular external things are causing ideas in us. This awareness allows us to use the idea as a sign of its external cause: for example, the sensation of white signifies whatever feature of objects causes that sensation. Representation is thus fundamentally causal: causality bridges the gap between reality and ideas. Consequently we have sensitive knowledge of things only through their powers, knowledge of their existence without knowledge of their essence. Each way in which things act on the senses gives rise to a phenomenally simple idea signifying a quality, or power to affect us, in the object. Some simple ideas, those of the 'primary qualities', solidity, extension, figure, motion or rest, and number (the list can vary) can be supposed to resemble their causes. Others, ideas of 'secondary qualities', colour, smell, taste and so forth, do not. We also form ideas of the powers of objects to interact.

Our idea of any sort of substantial thing is therefore complex, including ideas of all the qualities and powers by which we know and define that 'substance'. Additionally, the idea includes the 'general idea of substance', or possessor of the qualities, a placemarker signifying the unknown underlying cause of their union. Locke distinguishes between the general substance, matter, and the 'particular constitution' of matter from which flow the observable properties by which we define each sort of substance - gold, horse, iron and so on. This 'real constitution' or 'real essence' is distinguishable only relatively to our definition or 'nominal essence' of the species. Locke extends this conceptualist view of classification to individuation in a famous, still influential argument that a person is individuated, not by an immaterial soul, but by unifying and continuous consciousness.

Because their real essences are unknown to us, we are capable only of probable belief about substances, not of 'science'. In mathematics, however, real essences are known, since they are abstract ideas constructible without reference to reality. So too with ideas of 'mixed modes' and 'relations', including the ideas of social actions, roles and relationships which supply the subject-matter of a priori sciences concerned with law, natural, social and positive. The three legislators are God, public opinion and government. God's authority derives from his status as creator, and natural or moral law is his benevolent will for us. Locke's political theory concerns the authority of governments, which he takes to be, at bottom, the right of all individuals to uphold natural law transferred to a central agency for the sake of its power and impartiality. Economic change, he argues, renders this transfer imperative. In a state of nature, individuals own whatever they have worked for, if they can use it and enough is

left for others. But with land-enclosure (which benefits everyone by increasing productivity) and the institution of money (which makes it both possible and morally justifiable to enjoy the product of enclosure) this primitive property-right is transcended, and there is need for an authority to ordain and uphold rules of justice for the benefit of all. Any government, therefore, has a specific trust to fulfil, and should be organized so as best to safeguard this role. A ruler who rules in his own interest forfeits all rights, as a criminal at war with his subjects. Then rebellion is justified self-defence.

1 Life and main works

John Locke was born at Wrington, Somerset in England on 28 August 1632. His father was a small property owner, lawyer and minor official, who served on the side of Parliament in the civil war under the more influential Alexander Popham. Through Popham, Locke became a pupil at Westminster School, then the leading school in England. From Westminster he was elected in May 1652 to a Studentship at Christ Church, Oxford, conditionally tenable for life.

During the next fifteen years at Oxford Locke took his degrees (B.A. 1656, M.A. 1658) and fulfilled various college offices, becoming Tutor in 1661. Between 1660 and 1662 he wrote three manuscripts on issues of Church and State, individual conscience and religious authority, two now published together and known as *Two Tracts on Government*, and *An necesse sit dari in Ecclesia infallibilem Sacro Sanctae Scripturae interpretem? (Is it necessary to have in the church an infallible interpreter of holy scripture?)*. Although his answer to the last question was predictably negative, in the *Tracts* he expressed a less-than-tolerant view of conscientious religious unorthodoxy, assigning to rulers the right to determine details of religious observance for the sake of public peace. While Censor of Moral Philosophy at Christ Church in 1664 he completed the Latin manuscript now known as *Essays [or Questions] on the Law of Nature*, which presaged his mature views - both his general empiricism and his conception of moral obligation as an obligation to God to obey natural law. This work also rejects wayward and dogmatic appeals to conscience, in favour of reason based on experience.

The politics of religion, at the time a large part of politics, was not Locke’s only extracurricular interest. His reading-notes (‘commonplace books’) of this time indicate an interest in Anglican theology, and by 1658 he was reading and taking lecture notes in medicine with the assiduity appropriate to a chosen career. This interest extended to chemistry and, in the 1660s, to the new mechanical philosophy as expounded, for example, by Robert Boyle, whom Locke had met by 1660. Locke also read the main philosophical works of Descartes, and some Gassendi, but his record focuses on their versions of corpuscularianism, bypassing metaphysical and epistemological underpinnings (see Descartes, R. §§11-12; Gassendi, P. §§2, 4). On the evidence, natural philosophy attracted Locke more at this time than metaphysics, although the coarse empiricism of *Essays on the Law of Nature* is close to that of Gassendi. Yet Locke could hardly have remained ignorant of the battle among the new philosophers between ‘gods’ and ‘giants’ - between those, led by Descartes, in the Platonic-Augustinian metaphysical tradition and those, headed by Gassendi and Hobbes, who developed ancient empiricist and materialist theory.

In 1665 Locke’s university life was interrupted by a diplomatic mission to Brandenburg as secretary to Sir Walter Vane. About this time he decided against entering the church, but took the one way of nevertheless keeping his Studentship (without obligation to reside in Oxford) by transferring formally to medicine. In 1666 came a momentous meeting with Lord Ashley (Anthony Ashley Cooper, who became Earl of Shaftesbury in 1672), whose London household Locke subsequently joined in 1667. Here his medical and political interests alike received a more practical edge than they had previously possessed. He began collaborating closely with the pre-eminent physician, Thomas Sydenham, and in 1668 successfully supervised an operation on Lord Ashley to drain an abscess on the liver. In the years following he continued to act as medical advisor within Ashley’s circle, supervising the birth of Ashley’s grandson, later the philosophical Third Earl of Shaftesbury. A manuscript of this time in Locke’s handwriting (but perhaps wholly or partly by Sydenham), ‘De Arte Medica’, is strongly sceptical of the value of hypotheses, as opposed to experience, in medicine.

During this same period, presumably influenced by his patron, Locke wrote the manuscript *Essay concerning Toleration* (1667), departing from his earlier, nervously illiberal justification of constraint and advocating toleration of any religious persuasion not constituting a positive moral or political danger - provisos excluding, respectively, atheists and Roman Catholics. In 1667 Ashley became a member of the governing ‘cabal’ which

followed Clarendon's period as Lord Chancellor, and in 1672 became Lord Chancellor himself. Under Ashley, and for a while after Ashley's fall from office in 1673, Locke was involved in government. He began to work on economic questions, and for some years helped in the organization of the newly founded colony of Carolina. He was registrar to the commissioners of excise (perhaps a sinecure) from 1670 to 1675, secretary for presentations (in charge of ecclesiastical patronage) in 1672-3, and secretary and treasurer to the Council for Trade and Plantations (no sinecure) in 1673-4.

Nevertheless he found time for new intellectual interests. Not later than 1671 he put down for discussion by a group of friends what he later claimed (inaccurately, given *Essays on the Law of Nature*) to have been his first thoughts on the powers of the understanding. He found the topic sufficiently gripping for a more extensive treatment than such an occasion would have demanded in '*Intellectus humanus cum cognitionis certitudine, et assensus firmitate*' (The human intellect, the certainty of knowledge and the confirmation of belief), dated 1671, with a longer (and as strongly empiricist and imagist) redrafting in the same year entitled 'An Essay concerning the Understanding, Knowledge, Opinion and Assent' - the manuscripts now known as Drafts A and B of *An Essay concerning Human Understanding*.

In 1675 Locke moved to France, beginning at the same time to write his journal. He met physicians and philosophers, undertook a programme of reading in French philosophy and continued working on his 'Essay'. On returning to England in 1678, after the fabricated 'Popish plot', he was again caught up in politics and in attempts to exclude Charles' brother James from the succession. Charles dissolved Parliament in 1681, and Shaftesbury led a group of Whigs planning insurrection. During this period Locke probably wrote the bulk of the *Two Treatises of Government*; the first, at least, to support moves for James' exclusion, the second possibly later to advocate actual rebellion. He also wrote, with James Tyrrell, a long response (still unpublished, 1997) to Edward Stillingfleet's *Unreasonableness of Separation*, defending the position of nonconformists against Stillingfleet's criticisms. In 1682 Shaftesbury went into exile, dying soon after. When the Rye House plot to assassinate Charles and James was uncovered in 1683, Locke himself prudently moved to Holland, where he contacted other, more overtly active exiles. His connections provoked expulsion from his Christ Church Studentship in 1684, and at the time of Monmouth's rebellion he went into hiding to escape arrest. His intellectual activities continued unabated, the *Essay* being largely written by 1686. In 1685-6 he wrote *Epistola de Tolerantia (Letter concerning Toleration)*, perhaps in response to the revocation of the edict of Nantes. He made friends, and discussed theological questions, with the remonstrant Philippus van Limborch and Jean Le Clerc, publishing various items in the latter's journal, *Bibliothèque universelle et historique*, including a review of Newton's *Principia* (1686) and a ninety-two page abridgement of the *Essay* (1688).

In 1688 the 'Glorious Revolution' brought the deposition of James, and Locke returned to England the following year. He declined the post of ambassador to Brandenburg, accepted an undemanding post as commissioner of appeals (annual salary, £200) and set about publishing his writings. *Epistola de Tolerantia* was published pseudonymously in Holland in May 1689, and Popple's English translation followed within months. The *Two Treatises* were revised and published anonymously, and the *Essay* followed in December (with authorship acknowledged), although both books were dated 1690. *A Second Letter concerning Toleration* (1690) and *A Third Letter for Toleration* (1692) were in response to attacks by an Anglican clergyman, Jonas Proast. *Some Considerations of the Consequences of the Lowering of Interest and Raising the Value of Money*, partly based on the manuscript of 1668, was published in 1691 (dated 1692) against Parliamentary measures of the time. In 1691, Locke accepted the invitation of an old friend, Damaris Masham and her husband to live with them, as far as his concerns permitted, at Oates in Essex. Country life seems to have ameliorated the asthma which dogged his last years. *Some Thoughts concerning Education* (1693, revised 1695), a significant work in the history of educational theory, was based on a number of letters of advice to his friend, Edward Clarke. In 1694 came the second edition of the *Essay*, with important additions including a controversial chapter on identity. In 1695 he published a new work, once more anonymously, *The Reasonableness of Christianity*. John Edwards' attacks on its liberal, minimalist interpretation of Christian faith were rebutted in two *Vindications* (1695b, 1697a) (see Latitudinarianism).

Locke continued to be engaged on economic questions, and in 1695 he joined a committee to advise the Chancellor of the Exchequer on monetary policy. His recommendations, supported by further papers, were accepted. In 1696 came an important government appointment to the Council for Trade and Plantations, and for

four years he fulfilled fairly onerous duties on the Board of Trade for the considerable annual salary of £1,000. At the same time he engaged in an extended controversy with Edward Stillingfleet, who found the *Essay* theologically suspect. *A Letter to the Right Reverend Edward, Lord Bishop of Worcester* was followed by two further Letters in reply to Stillingfleet's Answers. Despite its controversial style, Locke's argument is often a cogent clarification of his position. The exchange prompted significant alterations to the fourth edition of the *Essay* (1700) and long passages were included as footnotes in the posthumously published fifth edition. In June 1700 Locke resigned from the Board of Trade, a sick man, and thereafter lived mostly at Oates. Pursuing a long-standing interest in biblical criticism, he set about the work which was posthumously published as *A Paraphrase and Notes on the Epistles of St. Paul*, an important contribution to hermeneutics (see Hermeneutics, biblical). In 1702 he wrote the reductive *Discourse of Miracles*, and in 1704 began a *Fourth Letter on Toleration*. On October 28th 1704 he died as Damaris Masham read to him from the Book of Psalms. For the last years of his life he was generally respected as, with Newton, one of Britain's two intellectual giants, a reputation undiminished by death.

2 The structure of Locke's empiricism

Locke's mature philosophy is 'concept-empiricist', but not 'knowledge-empiricist': he held that all our concepts are drawn from experience, but not that all our knowledge is based on experience. Yet his early position, in *Essays on the Law of Nature* and the first part of *Draft A*, was 'knowledge-empiricist' in just this sense - even the axioms of geometry gain assent 'only by the testimony and assurance of our senses' (*Draft A* I: 22-3). However, according to *Draft A*, when we find that certain relations hold without exception, we assume that they hold universally and come to employ them as 'standards' of measurement embodied in the meaning of our terms. Locke sees this as implying a choice: an axiom can *either* be interpreted as an 'instructive', but uncertain summary of experience, *or* as a quasi-definition, founded on experience but 'only verbal…and not instructive'. But later in *Draft A* he discards the notion that geometrical axioms can be interpreted empirically, taking them only in a sense in which they can be known by 'demonstration' or 'the bare shewing of things or proposing them to our senses or understandings' (*Draft A* I: 50) - that is, by intuitions with perceived or imagined instances (for example, diagrams) as their objects. At the same time he recognizes that mathematical propositions are not plausibly regarded as merely verbal. The possibility of alternative interpretations of universal propositions, *either* as certain, but verbal, *or* as instructive, but uncertain, is now restricted to propositions about substances, such as 'Man is rational'. Locke has shifted, in effect, from knowledge-empiricism towards a concept-empiricism which allows 'instructive' a priori knowledge (the last being the acknowledged ancestor of Kant's synthetic a priori - see Kant, I. §4).

Locke's intuitionism shapes his attack on the innatism characteristic of the Platonic-Augustinian-Cartesian tradition (see Innate knowledge). Starting with propositions, Locke rebuts the argument from alleged universal assent, or assent by all who have come to the use of reason. But ideas are what is before the mind in thought, and propositions are ideas in relation. Locke's underlying thesis is that to take either knowledge or ideas to be innately 'imprinted on the mind' in a merely dispositional sense (and they are clearly not actual in all human beings from birth) would be contrary to any intelligible notion of being 'in the mind': 'Whatever idea was never perceived by the mind, was never in the mind' (*Essay* I.iv.20). Locke concedes dispositional knowledge and ideas, retained by the memory and capable of being revived, but he understands both intentionality and knowledge in terms of perception, and finds nonsensical the notion of perception which never has been conscious and actual. This strongly intuitionist model rules out dispositional innatism as an intelligible possibility. Rationalist intuitionism, from Locke's point of view, is simply incoherent. And since the only dispositional ideas and knowledge are what is retained in the memory, what is before the mind as the object of intuition or demonstration must be experiential or sensory.

Locke also argues that there are no general maxims of logic or mathematics to which all assent when they come to the use of reason, since many rational but illiterate people never consider such abstract principles. He does not accept that reasoning merely consonant with logical principles is equivalent to assent to them, or, for example, that distinguishing two things is tacit employment of the idea of identity. Explicit abstract principles and ideas come late and with so much difficulty that people cannot agree on ideas of impossibility, identity, duty, substance, God and the like - just the ideas most supposed innately luminous. That rational people assent to certain propositions on first proposal is beside the point, since such people will only have understood the terms of the proposition in question by abstraction from experience. Then they will assent, not because the proposition is innate, but because

it is evident. To describe the bare capacity to perceive such truths as the possession of innate principles and ideas will make all universal knowledge innate, however specific or derived. Turning to practical principles and the idea of God, Locke appeals to anthropology to rebut the claim that any of these are universally recognized. The main thrust of his argument, however, is conceptual.

Locke’s empiricism has another central feature. Like Gassendi and Hobbes, he expressly accords independent authority to the particular deliverances of the senses (see Gassendi, P. §3). Descartes had argued that sensation requires interpretation employing innate, purely intellectual ideas even in order for us to conceive of its objects as independent bodies. For Descartes, moreover, natural sensory belief is defenceless in the face of sceptical argument - secure knowledge of the existence of bodies can only be achieved through a rational proof involving reflection on the role and mechanisms of sense (see Descartes, R. §9). This emphatic subordination of sense to reason Locke rejects just as firmly: the senses are ‘the proper and sole judges’ of the existence of bodies. He sees the senses as knowledge-delivering faculties in their own right, prior to any understanding of their mechanisms: ‘the actual receiving of ideas from without…makes us know, that something doth exist at that time without us, which causes that idea in us, though perhaps we neither know nor consider how it does it’ (*Essay* IX.xi.2). The sceptic’s doubt about the external world is a mere pretence, not to be taken seriously: ‘no body can, in earnest, be so sceptical, as to be uncertain of the existence of those things which he sees and feels’. Echoing Lucretius, Locke sees the reason employed in sceptical argument itself as standing or falling with the senses: ‘For we cannot act any thing, but by our faculties; nor talk of knowledge it self, but by the help of those faculties which are fitted to apprehend even what knowledge is’ (*Essay* IX.xi.3). Locke does identify features of sense-experience which militate against scepticism: for example, sensory ideas depend on physical sense-organs, and are systematically and unavoidably consequent on our situation; the deliverances of different senses cohere; there is a ‘manifest difference’ between ideas of sense and ideas of memory and imagination (most dramatically with respect to pain), as there is between acting in the world and imagining ourselves acting; and so on (*Essay* IX.xi.4-8). Yet all these considerations are simply ‘concurrent reasons’ which further, but unnecessarily confirm ‘the assurance we have from our senses themselves’ - ‘an assurance that *deserves* the name of knowledge’ (*Essay* IX.xi.3).

Locke’s explanation of the certainty and extent of ‘sensitive knowledge of existence’ hinges on his view that in sensation we are immediately aware, not only of sensations or ‘ideas’, but of their being caused by things outside us. We are thus able to think of the unknown cause through its effect in us: ‘whilst I write this, I have, by the paper affecting my eyes, that idea produced in my mind, which, whatever object causes, I call *white*; by which I know, that that quality or accident (i.e. whose appearance before my eyes, always causes that idea) doth really exist, and hath a being without me’ (*Essay* IX.xi.2). This claim ties in with another, that ideas of simple sensory qualities are always ‘true’, ‘real’ and ‘adequate’: ‘their truth consists in nothing else, but in such appearances, as are produced in us, and must be suitable to those powers, [God] has placed in external objects, or else they could not be produced in us’ (*Essay* II.xxxii.14). Simple ideas are ‘distinguishing marks’ which fulfil their function well enough whatever unknown difference lies behind the sensible distinction. But this function fits them for another, as terms in the natural language of thought. The idea of white signifies, that is *indicates*, its unknown cause, and also signifies, that is *stands for*, that feature of things in thought. So the limited causal knowledge that sensation supplies allows us to have contentful thought and knowledge of the external world. The idea of power extends such pretheoretical knowledge: our idea of the melting of wax, joined to the idea of active or passive power, can be employed as a sign of whatever in the sun melts wax, or of whatever in wax causes its melting. Consequently Locke decides to treat ideas of powers as simple ideas, and knowledge of powers as observational. The senses do not give knowledge of the essence or nature of bodies, but they do give knowledge of their existence, and enable us to distinguish between them.

3 Ideas of sensation and reflection: their retention and abstraction

Locke’s employment of the word ‘idea’ responds to a variety of antecedents. Like Descartes, he uses it ambiguously both for representative states (acts, modifications) of mind and, more frequently, for the represented objects as they are represented or conceived of, the so-called ‘immediate’ objects of perception and thought. To have an idea before the mind is generally, for Locke, to be contemplating something under a certain conception rather than contemplating a psychological state. To ‘perceive a relation between ideas’ is to perceive a relation between things-as-conceived-of. But Locke’s account also looks back to the Epicurean view of sensations as signs of their unknown causes in the motion of atoms or ‘corpuscules’ (see §2), a view which points away from the

Cartesian and scholastic presumption of intrinsically representative elements in thought towards a purely causal understanding of representation, treating ideas as blank sensory effects in the mind. Locke never resolves the tension between these different conceptions of an idea, although each of them is necessary to his theory.

Locke strongly opposes the Augustinian-Cartesian view that knowledge and truth consist in the conformity of human conceptions with God's conceptions, the divine ideas or archetypes employed in creation and revealed to us in our active use of reason. For Descartes, human reason is only accidentally involved with the senses, whereas for Locke there are no purely intellectual ideas. The task traditionally assigned to intellect - universal thought - Locke assigns to 'abstraction', taken to be the mind's in some sense separating out elements of raw experience and employing them as 'standards and representatives' of a class. What this means will be considered.

Although Locke sometimes writes that all words stand for ideas, ideas are the mental correlates of terms or names: that is, words that can stand in subject or predicate place. He adheres to the traditional view that 'particles', such as prepositions, conjunctions, the copula and the negative, signify, not ideas, but 'the connection that the mind gives to ideas, or propositions, one with another' (*Essay* III.vii.1). They do not *name*, but *express* 'actions of the mind in discoursing': for example, 'but' expresses various mental operations together named 'discretive conjunction'. The mental actions or operations expressed by 'is' and 'is not' are either the 'perception of the agreement or disagreement of ideas', which is Locke's definition of (at least, general) knowledge, or the 'presumption' of such a relation, which is Locke's account of belief or judgment. As commonly in earlier logic, merely considering a proposition is not distinguished from knowing or judging it to be true.

The aim of Book II of the *Essay* is to establish that all our ideas derive from experience: that is, that the way we conceive of the world (including ourselves) is ultimately determined by the way we experience the world. 'Experience' includes not only 'sense', but reflection ('reflexion') - not reflection in today's sense but reflexive awareness of our own mental operations. Platonists, Aristotelians and Cartesians all assigned the reflexive awareness of thinking to intellect rather than to sense. For Descartes, the innateness of such ideas as *substance*, *thought* and even *God* consists in the potentiality of their becoming explicit through the mind's reflecting on itself, and Leibniz argues accordingly that, simply by admitting reflection as well as sense, Locke admits innate ideas (see Leibniz, G.W. §8). Locke, however, claims that reflection, 'though it be not sense, as having nothing to do with external objects, yet it is very like it, and might properly enough be call'd internal sense' (*Essay* II.i.4). Thereafter he treats sense and reflection as theoretically equivalent (although reflexive knowledge of one's own existence is 'intuitive' rather than 'sensitive' - *Essay* IV.ix.3). This move not only extends the empiricist principle to such non-sensory notions as *willing*, *perceiving*, *contemplation* or *hope*, but also contradicts the Cartesian model of thought as transparent to itself, propounding a gap between how thinking appears to the subject and what it really is in itself - the latter being unknown. Locke also insists that reflection is second-order awareness, presupposing sense-perception as the first mental operation. And though 'ideas in the intellect are coeval with sensation' (*Essay* II.i.23), it seems that the mind must 'retain and distinguish' ideas before it can be said to 'have ideas' dispositionally, stored in the memory for employment as signifiers in thought. Ideas of reflection in particular are achieved only 'in time' - and here 'reflection' acquires some of its modern affinity with 'contemplation'. Children, Locke's accounts of both reflection and particles imply, can discern or compound ideas without having the ideas of discerning or compounding, and few of those who employ particles to *express* various mental actions ever pay them enough attention to be able to *name* them. Locke does assert that in the reception of ideas 'the understanding is merely passive', but he also allows that attention, as well as repetition, helps 'much to the fixing any ideas in the memory' (*Essay* II.x.3).

The 'retention' of ideas in the memory, therefore, is a necessary condition of discursive thought, and its description significantly echoes Hobbes' account of memory as 'decaying sense'. What decay are - 'it may seem probable' - images in the brain, and hostility to the separation of intellect from imagination pervades the *Essay*. Descartes' famous argument for such a separation - that we can accurately reason about a chiliagon although we cannot form a distinct image of it - is directly rebutted: the reasoning is made possible by our precise idea of the number of the sides (itself dependent on the technique of counting), not by a clear and distinct idea of the shape. 'Clear' ideas are, by definition, such as we receive 'in a well-ordered sensation or perception'. Locke's treatment of abstraction accords with such express sensationism. 'Abstract ideas' are particulars, universal only in 'the capacity, they are put into…of signifying or representing many particular things' (*Essay* III.iii.11). Locke means that in abstract thought the mind relates to, and employs, sensory images in a certain way, not that it manufactures

sense-transcendent objects of intellect. Abstract ideas are what we have *distinctly* before the mind in general thought, but distinctness may be achieved by 'partial consideration', not absolute separation: 'Many ideas require others as necessary to their existence or conception, which are yet very distinct ideas. Motion can neither be, nor be conceived without space' (*Essay* II.xiii.11-13). The very abstract ideas of *being* and *unity* are ideas of anything whatsoever considered as existing, or as one. Geometry gave Locke his paradigm of 'perception of the relation between ideas'. But where Cartesians saw the role of geometrical diagrams to be the stimulation of intellectual ideas, for Locke, as for Hobbes, the object of reasoning and source of 'evidence' is the diagram itself, whether actual or imagined. (Kant's 'intuition' owes something to Locke.) Given these structural features of his theory, it seems undeniable, as some have denied, that Locke's ideas are essentially sensory (or reflexive) images (see Hobbes, T. §4; Kant, I. §5).

4 Five sorts of idea

Book II of the *Essay* presents an alternative to Aristotle's doctrine of categories, the traditional typology of entities capable of being named or predicated (see Aristotle §7). That Locke's classification is of *ideas* rather than of *things* stresses that the categories are purely conceptual. He identifies five broad types: simple ideas, ideas of simple modes, ideas of mixed modes, ideas of substances and ideas of relations. Simple ideas come first in the Lockean order of knowledge, as substances come first in the Aristotelian order of being. Simple ideas are necessarily given in experience, whereas complex ideas can be constructed by 'enlarging' ('repeating') or 'compounding' simple ideas. Ideas of relations result from 'comparing' ideas. 'Abstracting' is more a matter of focusing on an idea or, better, an aspect of an idea, whether given or constructed, than of creating a new one (see §3). Locke sometimes acknowledges that the overarching compositional model is problematic in its application, but it is put into doubt even by his formal introduction of the notion of a simple idea. The ideas of the sensible qualities of a body, Locke claims, though produced by the same body, in some cases by the same sense, are evidently distinct from one another, each being 'nothing but *one uniform appearance*, or conception in the mind' (*Essay* II.ii.1). Yet to ascribe the conceptual distinctions between, for example, a thing's shape, its motion and its colour to a primitive articulation of *appearance* is to beg a crucial question.

Under the topic of simple ideas Locke expounds his famous distinction between primary and secondary qualities (*Essay* II.viii). Since the cause of a simple idea may be quite different in character from the idea itself, we should distinguish the idea in the mind from the corresponding quality (that is, the power to cause the idea) in bodies. Certain qualities, however, are necessary to our conception of bodies as such. These are the primary qualities, 'solidity, extension, figure, motion, or rest, and number', just those which figured in corpuscularian speculations. Locke's proposal (displaying the tension, described in §3 of this entry, between two conceptions of representation) is that in the perception of a primary quality the represented cause, the basis of the power in the object, is qualitatively *like* the idea caused: 'A circle and square are the same, whether in idea or existence' (*Essay* II.viii.18). Only this will allow that the action of external bodies on the senses is 'by *impulse*, the only way which we can conceive bodies operate in' (*Essay* II.viii.12) - an appeal to the seventeenth-century commonplace that mechanical explanations are peculiarly intelligible. But then ideas of 'colours, sounds, tastes, etc.', Locke's 'secondary qualities', must also be mechanically stimulated. Hence secondary qualities 'are nothing in the objects themselves, but powers to produce various sensations in us by their primary qualities, i.e. by the bulk, figure, texture, and motion of their insensible parts' (*Essay* II.viii.10). Ontologically they are in the same boat as the power of fire to cause pain or, indeed, its power to melt wax.

The idea of power itself Locke attributes to experience of regular patterns of change, giving rise first to expectations that 'like changes will for the future be made in the same things, by like agents, and by the like ways', and then to the thought that in one thing exists the possibility of being changed and in another 'the possibility of making that change' (*Essay* II.xxi.1). So we form the idea of power, active and passive: the power of fire to melt wax and the power of wax to be melted are aspects of fire and wax known and identified only through their joint effect. The idea of power is thus a place-marker for attributes which could in principle be known more directly.

The ideas or experiences of pleasure and pain are important simple ideas, since they are responsible for our ideas of good and evil, and are 'the hinges on which our passions turn' (*Essay* II.xx.3). (This hedonistic theory of motivation and value is examined in §9 of this entry.)

‘Simple modes’ constitute another problematic category. Locke starts with modes of extension, the subject-matter of geometry, with which he compares modes of duration. Here his thesis is that we acquire ideas of particular modes of extension (that is, determinate lengths and figures) or duration (that is, periods) in experience, and can then repeat (or divide) them so as to construct ideas of possible lengths, figures or periods not previously experienced. Roughly, ‘modification’ here is compounding like with like. The same model supplies Locke’s account of ideas of numbers, achieved by the repetition or addition of units, aided and ordered by the linguistic technique of counting. Yet he also recognizes qualitative simple modes, effectively conceding that ideas of different ‘shades of the same [experienced] colour’ are constructible. Even with quantitative ‘modes’, where the ‘repetition’ model has some plausibility, it is problematic what is a simple idea. The idea of determinable *extension* is a plausible candidate, with its determinates as ‘modes’, but the repetition model presupposes simple units. Locke impatiently responds that the smallest sensible point ‘may perhaps be the fittest to be consider’d by us as a *simple idea* of that kind’ (*Essay* (5th edn) II.xv.5n.), but he was evidently more concerned to argue that ideas of novel determinate figures are *somehow* constructible from what has been given, and so to subvert a Platonic-Cartesian argument for innateness, than to insist on the adequacy of a rigid compositional model.

Another target in Locke’s account of simple modes is Descartes’ conceptual identification of space and matter in the thesis that the essence of matter is extension. For Locke, both the essence of matter and the nature of space are unknown. He argues that our idea of a vacuum is not contradictory, since our ordinary idea of body includes solidity as well as extension, but he declines to choose between relational and realist theories of space. Yet comparison of the *Essay* with earlier notes and drafts indicates that, having first held a Hobbesian relational view, Locke came gradually to favour a realism close to that of Newton (see Descartes, R. §§8, 11; Newton, I. §4).

Ideas of mixed modes arise with the combination of unlike simple ideas, as in the idea of a rainbow. But Locke’s paradigms are ideas of human actions and institutions, the materials of demonstrative moral and political theory. Like ideas of geometrical figures, ideas of mixed modes can properly be formed without regard to what exists. Ethical thought is none the worse for being about a virtue or motive or political constitution which is nowhere actually instantiated. Ideas of substances are different, for they concern the real rather than the ideal: ‘When we speak of *justice*, or *gratitude*…our thoughts terminate in the abstract ideas of those virtues, and look not further; as they do, when we speak of a *horse*, or *iron*, whose specific ideas we consider not, as barely in the mind, but as in things themselves, which afford the original patterns of those ideas’ (*Essay* III.v.12). Moreover, whereas ideas of substances are formed on the presumption that the complex idea represents a really or naturally united thing, the unity of mixed modes is essentially conceptual. Indeed, ‘Though…it be the mind that makes the collection, tis the name which is, as it were the knot, that ties them fast together’. Different languages slice up the field of human life and action in different ways, determined by the practices and priorities of the communities that speak them. This thesis can be extended to natural modes such as freezing, since even here it is the term tied to a striking appearance, not a natural boundary, which slices out the particular process from the general process of nature. That, Locke plausibly assumes, is not how it is with horses.

The chief thought behind Locke’s somewhat confusing account of ideas of substances is that our idea of a thing or stuff is a compound of ideas of its qualities, but the thing itself is not a compound of qualities (*Essay* II.xxiii). The substance-accident structure is a feature of our ideas and language, not a structure in reality. It is a feature which marks our ignorance of the underlying nature of things, since we always conceive and talk of a substance as a *thing* possessing certain qualities, that is, as a ‘*substratum*, in which [the qualities] do subsist, and from which they do result, which therefore we call substance’. The mistake of dogmatic philosophers is to think that they can form *simple* conceptions of substances matching their unitary natures. Aristotelians are so misled by language that, just because, ‘for quick despatch’, we employ one name, ‘gold’ or ‘swan’, they think it a ‘simple term’ corresponding to a ‘simple apprehension’. Cartesians take the simple essences of matter and spirit to be extension and thought. Yet so far are we from catching the nature of any thing in our *complex* idea of it that, if it is asked what the subject is of the qualities by which we define it (the colour and weight of gold, for example), the best answer we can give is ‘the solid extended parts’, that is, the mechanistic ‘corpuscularian’ hypothesis as advanced by Boyle. If it is asked in turn ‘what it is, that solidity and extension inhere in,’ we can only say, ‘we know not what’. Our idea of the substance is of ‘nothing, but the supposed, but unknown support of those qualities, we find existing, which we imagine cannot subsist, *sine re substante*, without something to support them’. Such an idea is ‘obscure and relative’. Ideas of specific substances are ‘nothing but several combinations of simple ideas,

co-existing in such, though unknown, cause of their union as makes the whole subsist of itself' (*Essay* II.xxiii.6). Locke's point is that no theory, not even the corpuscular hypothesis, gives an account of the ultimate nature of things.

Finally come ideas of relations - father, son-in-law, enemy, young, blacker, lawful and so on (*Essay* II.xxv-xxviii). Like ideas of modes, ideas of relations can properly be constructed without regard to reality, in particular if they are conventional relations. Adequate ideas even of natural relations, Locke claims, are possible without adequate ideas of the things related: we can grasp the essence of fatherhood without knowing the essence of man or even the mechanisms of reproduction. His point is that the biological details are irrelevant to the rights and duties of a father - a question rationally determined in his own attack on patriarchalism in *Two Treatises*. From this point of view, relations are theoretically close to modes. Yet Locke does allow certain relations to have peculiar ontological significance. Causal, spatial and temporal relations are universal relations which pertain to all finite beings. Identity and diversity are so too: a thing is diverse from anything existing in a different place at the same time, 'how like and indistinguishable soever it may be in all other respects', and the continuity of individual substances is spatio-temporal. The last important type of relations to be picked out for special discussion is that of moral relations, or the relations of actions to some law 'whereby good or evil is drawn on us, from the will and power of the law-maker' (*Essay* II.viii.5).

5 Substances, mixed modes and the improvement of language

On Locke's account of communication (*Essay* III.i-ii), names should, by common convention or special agreement, excite in the hearer's mind just the same ideas as they are associated with in the speaker's mind. Collaborative progress in the sciences depends on 'clear and distinct' or 'determined and determinate' ideas - that is, on consistent and agreed association of ideas and words (*Essay* II.xxix; compare 'Epistle to the Reader'). Locke's discussion of language is shaped by his belief that these conditions of the transference of knowledge were in his time commonly unsatisfied, especially in two domains. First, there was no agreed classification of 'substances' (living things and chemicals) based on careful observation and experiment. Second, the ideas associated with the names of mixed modes often varied both in the usage of different people and in that of the same person at different times. Two mistakes in particular disguise these shortcomings of language. The first is the assumption that a common set of words ensures a common language in the full sense, with a shared set of meanings. So people may argue about 'honour' and 'courage' without realizing that they mean different things, or nothing at all, by the words. The second mistaken assumption is that words have meaning by standing for things directly, as if the meaning of 'salt', 'gold' or 'fish' were fixed demonstratively, by what is named. The first assumption chiefly corrupts our thought about mixed modes, the second relates 'more particularly, to substances, and their names' (*Essay* III.ii.5). Locke's radical and influential views about the latter will be considered first.

The 'idea of substance in general' employed in ideas of specific substances is the idea of something unknown underlying the attributes known by experience (see §4 of this entry). Many have objected, following Leibniz, that here Locke confusedly postulates ignorance of the subject of attributes which is not ignorance of attributes of the subject. Yet he holds that our ignorance of 'the substance of body' and 'the substance of spirit' is an ignorance of the *natures* of these things - ignorance manifested in our inability to understand the internal cohesion or (he adds in later writings) mutual attraction of bodies, or to explain what thinks in us, and how it does so. His approval of the corpuscularian hypothesis and Newton's mechanics is qualified - the best available physical theory leaves too much unexplained to be the whole truth (Newton did not disagree). The idea of substance is a place-marker for essences which are unknown, but knowable, if possibly not by human beings (see Newton, I.).

One feature of Locke's theory which has made difficulties for the present interpretation is the distinction he makes between substance and 'real essence'. The real essence of a thing, Locke says, may be taken for 'the very being of a thing, whereby it is what it is', the 'real internal, but generally in substances, unknown constitution of things, whereon their discoverable qualities depend' (*Essay* III.iii.15). Nevertheless, '*essence*, in the ordinary use of the word, relates to sorts' (*Essay* III.vi.4). Species and genera, or sorts of things, Locke asserts, are creatures of the understanding, with membership determined by abstract ideas made on the basis of experienced resemblances, not by the presence in each of a specific form, or by a common derivation from a divine archetype. Ultimately it is a matter of arbitrary definition which observable resemblances we count as necessary for membership of this or that named sort. It is not just that specific real essences are unknown, since (Locke argues) even if we did know the real

constitution of things as well as clock-makers know the works of clocks, it would still be up to us where to draw the boundaries between species, and what to include in our abstract ideas or ‘nominal essences’. The real essence of a species can therefore only be ‘that real constitution…which is the foundation of all those properties, that are combined in, and are constantly found to co-exist with, the *nominal essence*’ of the species (*Essay* III.vi.6). Here, the model is that of a universal matter determinately modified as a variety of particles interacting mechanically so as to constitute the material things of ordinary experience. Since at the fundamental level these observable quasi-machines differ from one another merely quantitatively, and can do so by indefinite degrees, there are no absolute boundaries among them. There are only the discernible resemblances and differences consequent on their underlying mechanical differences - ‘the wheels, or springs…within’. Even more certainly our actual classification is not based on knowledge of any such boundaries. Talk of the real essence of a species, and the distinction between its ‘properties’ and its ‘accidents’ (’properties’ flowing from the essence), are therefore, contrary to Aristotelian assumptions, *de dicto* and relative to the nominal essence defining the name of that species (see Aristotle §8; De re/de dicto; Essentialism).

This conception of a real essence assigns it a role closely related to that of substance. What, after all, is the ‘unknown cause of the union’ of any of the ‘combinations of simple ideas’ by which ‘we represent particular sorts of substances to ourselves’, if not the real essence underlying the nominal essence in question? Yet Locke sometimes distinguishes both the notion and knowledge of real essence from the notion and knowledge of substance. That is not, however, because the ‘substance’ is an irremediably unknown subject underlying even essence, but because it is the common stuff of a variety of species of things, ‘as a tree and a pebble, being in the same sense body, and agreeing in the common nature of body, differ only in a bare modification of that common matter’ (*Essay* II.xiii.18). The unknown modification is the specific ‘real essence’, and the equally unknown general nature of matter is the ‘substance’. Locke also envisages deeper differences of kind between substances: ‘God, spirits and body’ are all ‘substances’ only because we think of each of them indeterminately as *something*, not because of a shared nature. But by the same token we distinguish spirit and body only because we cannot understand how matter could think, not because we can grasp their separate essences, as Descartes had supposed (see Descartes, R. §8). Indeed, since we are equally unable to understand how spirit and body might interact, or how spirits could occupy places, the issue between materialist and immaterialist accounts of minds is for Locke undecidable, and at best a matter for speculation.

Locke’s corpuscularian conception of a world of machines, resembling and differing from one another by continuous degrees, is consonant with his independent epistemological conviction that names have meaning only through association with ‘ideas’, rather than directly with ‘things as really they are’. Together they motivate his programme for improving natural classification which advocates, not the allegedly impossible Aristotelian ideal of identifying the natural hierarchy of genera and species, but general agreement on a practically useful way of gathering and ordering the things in the world, taking into account such dependable concomitances of qualities and powers as appear to careful observation and experiment. Locke saw the future of biology and chemistry - and even of mechanics - in descriptive ‘natural history’, justifiable as a useful, orderly record of dependable means to ends but falling short of systematic ‘science’. Despite its apparent pessimism, his view has survived in biological taxonomy as a continuous tradition of scepticism as to the reality of our taxonomical divisions. In semantic theory, Locke’s broad conception of how the names of substances have meaning has only recently been eclipsed by a quasi-Aristotelian view (see Kripke, S.A.; Putnam, H.).

Locke saw equal need for a programme of agreeing definitions in ethics, where his target is less the notion that moral and political terms name independent realities, than the assumption that the very existence of a word in a language ensures that it has a fixed, common meaning. ‘Common use’, Locke concedes, ‘regulates the meaning of words pretty well for common conversation’ (*Essay* III.ix.8) - for the ‘civil’ rather than ‘philosophical’ use of words. But where precision is required, as in the establishment or interpretation of a law or moral rule, reliance on ordinary usage leaves us vulnerable to the trickery of rhetoricians who prove bad qualities good by shifting the meaning of terms; or to the subtleties of interpretors, whether of civil or revealed law, who render unintelligible what started off plain. The remedy is to give the names of virtues and vices, and of social actions, roles and relations the fixed and unequivocal definitions necessary for a clear and unwavering view of right and wrong, ‘the conformity or disagreement of our actions to some law’.

6 Knowledge and belief

Like Platonists and Cartesians, Locke drew a strong distinction between knowledge and belief (also called opinion, judgment, or assent), but the ground and placing of this division between two forms of propositional ‘affirmation’ differed from theirs fundamentally. As the distinction is expounded in Book IV of the *Essay*, universal knowledge or ‘science’ does not have special objects, whether a transcendent intelligible world in the mind of God or innate intellectual ideas. Its difference from general belief lies in the way in which ideas are related in the mind. In universal knowledge, the ‘connection and agreement, or disagreement and repugnancy’ of ideas is ‘perceived’, whereas in belief it is ‘presumed’ on the basis of ‘something extraneous to the thing I believe’. To follow a proof gives knowledge of the conclusion, whereas to accept the conclusion on the authority of a mathematician constitutes only belief. Similarly in the case of ‘sensitive knowledge’ of particular existence, what we ourselves perceive we know to be so, but what we infer, or accept on testimony, we merely believe.

Knowledge, as well as assent, is subject to ‘degrees’: there are degrees, not only of probability, but of ‘evidence’. The first degree of knowledge is intuitive knowledge, in which the mind ‘perceives the truth, as the eye doth light, only by being directed toward it’. Intuition ‘leaves no room for hesitation, doubt, or examination’. The second degree is demonstrative knowledge, where the truth is perceived by the aid of one or a chain of ‘intermediate ideas’. Doubt or mistake is possible at any point in the sequence with respect to connections not currently in view. Hence, ‘Men embrace often falsehoods for demonstration’. Locke’s chief model for ‘intermediate ideas’ is geometrical: for example, the lines employed in the intermediate steps of the Euclidean proof which allow us to see that the angles of a triangle are equal to the angle on a straight line. Although his conception of intuition can seem Cartesian, the profound difference is that, for Locke, ideas which are objects of intuition are essentially a product of sense (including reflection) and imagination. As *Draft B* puts it, the angles and figures I contemplate may be ‘drawn upon paper, carved in marble, or only fancied in my understanding’ (*Drafts* vol. 1: 152). Consequently Locke often talks as if we can *literally* perceive a necessary relation between ideas. Another difference from Descartes, as also from Hobbes, is that he rejects the pretensions of proposed analytical methods to uncover self-evident principles from which the phenomena can be deduced.

The third degree of knowledge is sensitive knowledge of the existence or ‘co-existence’ of qualities in external things. Locke’s first introduction of this category seems tentative, even an afterthought, as if it is called knowledge only by courtesy. In order to fit his main definition of knowledge it has to be interpreted as the perception of the agreement of ideas of sensible qualities with the idea of existence, an analysis Locke unsurprisingly declines to develop. Yet ‘sensitive knowledge of existence’ does straightforwardly satisfy his other definition of knowledge: what is known in sensitive knowledge (that is, that something external is causing an idea of sense) is known directly, ‘perceived’ and not inferred (see §2 of this entry). Locke was writing in a context in which, despite Gassendi’s Epicurean claim that sensory knowledge is the most evident of all, it was widely assumed that knowledge in the full sense comprises only knowledge of necessary first principles, demonstrated ‘science’, and perhaps reflexive knowledge. Locke wanted both to concede to orthodoxy that the evidence and certainty of our sensory knowledge is not as high as that of intuition and demonstration, and to insist that, nevertheless, ‘sensitive knowledge of existence’ does give a degree of immediate certainty and ‘deserves the name of knowledge’.

Knowledge is also categorized in terms of four propositional relations (forms of ‘agreement’) between ideas, namely ‘identity (or diversity)’, ‘relation’, ‘necessary connection or coexistence’ and ‘existence’ (*Essay* IV.i). By ‘identity’ Locke intends tautologies such as ‘Gold is gold’ and ‘Red is not blue’. Intuitive knowledge of such identities is achieved simply by discerning ideas. The category also includes such truths as ‘Gold is a metal’ or ‘Gold is malleable’, when the property predicated is included in the thinker’s definition of gold. Thus ‘identity’ covers all and only ‘trifling’ or ‘verbal’ propositions (see §2 of this entry).

The categories, ‘relation’, ‘necessary connection or coexistence’, and ‘existence’, on the other hand, together include all ‘instructive’ propositions. The category, ‘relation’, in part a response to Locke’s earlier difficulty over the informativeness of mathematics (see §2 of this entry), also marks his rejection of analytical methods in science. As well as geometrical axioms and theorems, ‘relation’ presumably includes more exciting Lockean principles: as that, if anything changes, something must have a power to make it change; that, if anything exists, something must have existed from eternity; and that a maker has rights over his artefact. Categorical propositions about natural things, however, fall either under ‘existence’ or under ‘necessary connection or coexistence’. Our own existence is known intuitively, God’s existence demonstratively (Locke employs an idiosyncratic hybrid of the cosmological

and teleological proofs), and, as discussed, the existence of bodies by sense. The category ‘necessary connection or coexistence’ owes its disjunctive name to a rather complicated relation between particular and universal propositions. Particular *coexistences* are perceived by sense, for example, when we simply observe that yellowness, heaviness and the metallic qualities coexist in a particular subject together with malleability (that is, that this gold is malleable), without perceiving *necessary connections* between them. Locke assumes, however, with most mechanists, that necessary connections do hold between universally coexistent properties even if we cannot perceive or grasp them. Since he contends that no natural science based on the essences of substances has been achieved, he offers only very limited examples of perceived necessary connections, as ‘whatever is solid is impenetrable’ and ‘a body struck by another will move’. (According to the short, posthumously published *Elements of Natural Philosophy*, the laws of inertia are evidently necessary, but the law of gravity is based only on experience.) In the absence of knowledge, beliefs in universal coexistences (for example, that all gold dissolves in aqua regia), when we *presume* unperceived connections, may be inductively based on sensitive knowledge of particular coexistences. That is descriptive natural ‘history’, not ‘science’. In general, if the idea of a particular quality is deducible from the idea of a substance, that is only because the predication of that quality is an identity: that is, universal propositions about substances, if certain, are ‘trifling’ and, if ‘instructive’, are uncertain (see §2 of this entry). In contrast, instructive a priori sciences are possible just because their objects are constructed by us: our ideas of simple or mixed modes, formed without essential reference to actuality, themselves constitute the subject-matter of mathematics and ethics. In other words, these demonstrative sciences are possible, as natural science is not, just because they deal, hypothetically, with abstractions.

The degrees of assent are ‘Belief, Conjecture, Guess, Doubt, Wavering, Distrust, Disbelief, etc.’ (*Essay* IV.xvi). Probability is ‘the measure whereby [the] several degrees [of assent] are, or ought to be regulated’. When assent is unreasonable, it constitutes ‘error’. Reasonable assent is regulated according to the proposition’s conformity with the thinker’s own experience or the testimony of others. The proposition may concern ‘matters of fact’ falling within human experience, or else unobservables lying ‘beyond the discovery of our senses’. Locke identifies four broad degrees of probability with respect to ‘matters of fact’: (1) when the general consent of others concurs with the subject’s constant experience; (2) when experience and testimony suggest that something is so for the most part; (3) when unsuspected witnesses report what experience allows might as well be so as not; and (4) when ‘the reports of history and witnesses clash with the ordinary course of nature, or with one another’ - a situation in which there are no ‘precise rules’ for assessing probability. Finally, with respect to unobservables, ‘a wary reasoning from analogy’ with what falls within our experience ‘is the only [natural] help we have’ and the only ground of probability (see Descartes, R. §4). Although Locke, in striking contrast to Descartes, brings probability into the centre of epistemology, ‘belief’ is always treated as a practical surrogate for ‘knowledge’, and he takes induction itself to be grounded on the assumption of underlying, unknown necessary connections: ‘For what our own and other men’s constant observation has found always to be after the same manner, that we with reason conclude to be the effects of steady and regular causes, though they come not within the reach of our knowledge’ (*Essay* IV.xvi.6).

Another deliberate and radical difference from Descartes relates to the role of will in cognition. For Locke, knowledge is like sense perception: we may choose where and how hard to look, but we cannot then choose what we see. Belief is similar: ‘Assent is no more in our power than knowledge…. And what upon full examination I find the most probable, I cannot deny my assent to’ (*Essay* IV.xx.16). Yet we are morally responsible for both error and ignorance in so far as it results from our not employing our faculties as we should. In a number of chapters of the *Essay*, Locke examines the causes of error, finding them, with many writers of his time, in the same appetites, interests, passions, wayward imaginings and associations of ideas as may motivate voluntary actions. Linguistic confusion, and its deliberate exploitation (see §5 of this entry), sometimes plays a role, and sometimes, like Malebranche and others, Locke has direct recourse to physiology, explicitly merging his explanations of error with explanations of madness. In contrast to Hobbes, he places the merely habitual ‘association of ideas’ in the pathology of ‘extravagent’ thought and action: ‘all which seems to be but trains of motion in the animal spirits, which…continue on in the same steps…which by often treading are worn into a smooth path, and the motion in it becomes easy and as it were natural’ (*Essay* II.xxxiii.16). But culpable error arises, on Locke’s official view, when we ‘hinder both knowledge and assent, by stopping our enquiry, and not employing our faculties in the search of any truth’ (*Essay* IV.xx.16). It is the failure to use our power to pause for ‘full examination’ which leaves a space for beliefs motivated by interests and passions. But this two-stage model - the first stage voluntary, the second

involuntary - proves too difficult to maintain, and sometimes passions and interests are taken to act on the will *between* enquiry and judgment, by distorting our ‘measures of probability’ themselves. Locke’s approach is more common-sensical than that of Descartes, but the psychology of motivated error is a hard nut which he also failed to crack.

7 Faith, reason and toleration

Locke’s views on belief, probability and error owed much to traditional philosophy of religious belief, and to the great debate of his century about the relationship between faith and reason. He was strongly influenced by writers in the Anglican ‘probabilist’ tradition, who argued for toleration within the Church with respect to all but an essential core of Christian dogma. William Chillingworth had rejected as absurd the traditional conception of a moral requirement to have ‘faith’ in the sense of a conviction equal to that of knowledge but beyond what is rationally justified. To recognize a proposition as probable to a certain degree is to believe it just to that degree. Revelation therefore cannot be a basis for belief distinct from probability, but is something the significance of which has to be rationally assessed, capable at best of increasing the probability of certain propositions. Similarly for Locke, when revelation grounds belief that would otherwise be improbable, that is just one natural reason outweighing another: ‘it still belongs to reason to judge of the truth of its being a revelation, and of the signification of the words, wherein it is delivered’ (*Essay* IV.xviii.8). For if ‘reason must not examine their truth by something extrinsical to the perswasions themselves; inspirations and delusions, truth and falshood will have the same measure’ (*Essay* IV.xix.14).

Accordingly, like Chillingworth, More and others, Locke combined a purportedly reasonable acceptance of the Bible as revelation with a critical approach to its interpretation, taking into account that it was written by men in particular circumstances. An alleged revelation which conflicts with what is naturally evident loses its claim to be revelation. Certain revealed truths (such as the Resurrection) lie ‘beyond the discovery of our natural faculties, and above reason’, but Locke had little time for mysteries: ‘to this crying up of faith, in opposition to reason, we may, I think, in good measure, ascribe those absurdities that fill almost all the religions which possess and divide mankind’ (*Essay* IV.xviii.7, 11). Locke took the existence of God and the content of moral law to be demonstrable by reason, and, according to *The Reasonableness of Christianity* and its *Vindications*, the only essentially revealed truth of the New Testament is that Christ is the Messiah, promising forgiveness of sins to those who sincerely repent and do their imperfect best to keep the law of nature. The Bible also makes that law plain to those without the leisure or capacity to reason it out - a difficult enough task for anyone, as Locke ruefully acknowledges. The meaning of scripture is thus for Locke primarily moral, and the ‘truth, simplicity, and reasonableness’ of Christ’s teaching is itself a main reason for accepting it as revelation. Saving faith involves works, not acceptance of ‘every sentence’ of the New Testament under this or that preferred interpretation.

Much the same goes for immediate revelation. Even the genuinely inspired would need proofs that they really were inspired, and the errors of commonplace ‘enthusiasm’ are ascribed, as by More, to physiology, ‘the conceits of a warmed or overweening brain’. The advocate of immediate personal revelation over reason ‘does much what the same, as if he would persuade a man to put out his eyes the better to receive the remote light of an invisible star by a telescope’ (*Essay* IV.xix.4). Divine illumination necessarily depends on, and is not separable from, the natural light - ‘reason must be our last judge and guide in everything’. Locke echoes Chillingworth’s basic principle: the lover of truth, unbiased by interest or passion, will not entertain ‘any proposition with greater assurance than the proofs it is built upon will warrant’. The implication of this standard, in the actual circumstances of life, is toleration: ‘For where is the man, that has incontestable evidence of the truth of all that he holds, or of the falshood of all he condemns; or can say, that he has examined, to the bottom, all his own, or other men’s opinions?’ (*Essay* IV.xvi.4).

Locke’s *Letter on Toleration*, the mature fruit of considerably more unpublished writing directly on the issue, links his epistemology with his political thinking. Belief is not something that can be commanded or submitted to the authority of the government, whose concern is not with saving souls but the preservation of property. Necessarily each individual must judge as they see fit, and the truth needs no help, having its own efficacy. But the right to toleration is nevertheless viewed in the context of the right and duty to seek salvation and true doctrine without harm to others, harm which is at least threatened by all who deny the authority either of moral law or of the established government. Atheists therefore forfeit the right in principle, and Roman Catholics as a matter of

political fact. (See Latitudinarianism; Socinianism.)

8 Personal identity

The main aim of the chapter of the *Essay* entitled ('Of Identity and Diversity' (II.xxvii) is to explain how immortality is compatible with materialism. In order to maintain an agnostic neutrality on the question of the immateriality of the soul, Locke had, first, to rebut the Cartesian claim that self-awareness supplies a clear and distinct idea of a simple, continuously existing substance; and, second, to show that the metaphysical issue is irrelevant to 'the great ends of morality and religion' (*Essay* IV.iii.6). He argues that, although the moral agent is indeed the continuously existing, rational, self-aware subject of consciousness, the 'person', the identity of this subject over time is determined by the continuity of unitary consciousness itself, not the continuity of an immaterial soul. Locke can therefore accept the Resurrection and Last Judgment as tenets of his 'reasonable' Christianity, without commitment to dualism, on the supposition that the consciousness of the resurrected person is continuous, through memory, with that of the person who died. This conclusion avoids an objection to his concept of demonstrative ethics as a science of modes, that morality relates to 'man', a substance, not a mode. His response is that morality concerns, not 'man' as a biological species, but 'man' as rational, the 'moral man', indeed all rational beings. 'Person', as he puts it, is a 'forensic term'.

Locke's argument starts from the claim that questions of identity over time are always questions as to the continuous existence in space of something of a certain kind, and that difficulties may be avoided by 'having precise notions of the things to which it is attributed'. The identity of non-substances is parasitic on that of substances: 'All other things being but modes or relations ultimately terminated in substances', their identity will be determined 'by the same way' (*Essay* II.xxvii.2). Locke holds that events and processes ('actions') are not strictly identical from moment to moment, each part of what we consider one process being distinct from every other part. Substances, however, genuinely continue to exist from moment to moment. The identity of 'simple substances' - material atoms and the presumed simple 'intelligences' - is straightforward. Each excludes others of the same kind out of its place by its very existence - a principle definitive of identity. But difficulties arise with compound substances. Strictly, a body composed of many atoms is the same just as long as the same atoms compose it - yet 'an oak, growing from a plant to a great tree, and then lopped, is still the same oak'. Locke's explanation is that 'in these two cases of a mass of matter, and a living body, *identity* is not applied to the same thing' (*Essay* II.xxvii.3). Although he does not clearly distinguish the two views, he seems to hold individuation, rather than the identity-relation, to be kind-relative. A plant or animal is not just 'a cohesion of particles anyhow united', but such an organization of parts as enables the continuation of its characteristic life, for example, as an oak. In fact the *species* of the living thing is irrelevant to Locke's theory (fortunately, given his view that the definition of 'oak' will differ from speaker to speaker). The essential claim is that life is a principle of unity and continuity distinct from simple cohesion, thus allowing a living thing and the mass of matter that momentarily composes it so to differ in kind as to be capable of occupying the same place at the same time.

Locke defines *person* as 'a thinking intelligent being, that has reason and reflection, and can consider itself as itself, the same thinking thing at different times and places' (*Essay* II.xxvii.9). His thesis is that, just as life constitutes a distinct individuative principle of unity and continuity, so does reflexive consciousness. He argues for the logical independence of the continuity of consciousness from both the continuity of substance (whether supposed material or immaterial, simple or complex) and the continuity of animal life by a series of imagined cases: for example, for someone now to possess Socrates' soul would not make him the same person as Socrates, unless he remembered Socrates' actions as his own; whereas if souls are the seat of consciousness, and the soul of a prince could migrate to the body of a cobbler, 'everyone sees he would be the same person with the prince, accountable only for the prince's actions. But who would say it was the same man?' (*Essay* II.xxvii.15). Locke viewed such cases, not necessarily as real possibilities, but as compatible with our partial understanding of things, our *ideas*: 'for such as is the idea belonging to that name [namely 'person', 'man' or 'substance'], such must be the identity'. Yet in the crucial case of the Resurrection, we are left wondering how continuous existence through time - not to speak of space - is achieved simply by a fit between present consciousness and past experience and actions. Indeed, as Berkeley and Reid argued, memory-links seem both too little and too much for the continuity of a substantial thing. Yet, despite these and other difficulties for Locke's theory, it set the agenda for subsequent discussion and versions of it still have adherents (see Personal identity).

9 Ethics, motivation and free will

With Locke's conviction that a demonstrative ethics is possible went a belief that what stood in its way was the deplorable slipperiness, openly encouraged by the practice of rhetoric, of a moral language in which terms are not consistently tied to ideas (see §5 of this entry). Both were consonant with his apparently early conviction that Natural Law theory, as pursued by such as Hooker and Grotius, is capable of development into a full account of our duties to God and our fellows - even though he had first seen Natural Law as empirically based (see §3 of this entry). But Natural Law theory also gave him what could not be supplied by the conception of a quasi-geometrical system of rights and duties flowing from the definitions of mixed modes and relations: the conception of an unconditional obligation to act in accordance with moral principle against what we might otherwise desire (see Natural Law).

In the *Essay* the argument starts, as might be expected, with the question of how our basic concepts of value are derived from experience. Locke has no doubt about what it is in experience that makes anything matter to us. Like other empiricists of his time, he is both a psychological and an ethical hedonist. Pleasure and pain supply not only our sole motives but also our ideas of good and evil: 'That we call *good* which is *apt to cause or increase pleasure*, or *diminish pain in us; or else to procure, or preserve us the possession of any other good, or absence of any evil*' (*Essay* II.xx.1). The passions are 'modes' of pleasure and pain arising from, or involving, value-judgments: thus hope is 'that pleasure in the mind, which every one finds in himself, upon the thought of a probable future enjoyment of a thing, which is apt to delight him'; fear is 'an uneasiness of the mind, upon the thought of a future evil likely to befall us' (*Essay* II.xx.9-10). Desire is the 'uneasiness a man finds in himself upon the absence of any thing, whose present enjoyment carries the idea of delight with it' (*Essay* II.xx.6). This theory of motivation faces certain problems. First, how do we get from judgments of good and evil, of what conduces to pleasure and pain, to judgments of right and wrong, of what we morally ought or ought not to do? Second, having got there, if the passions, as modes of pleasure and pain, constitute our only motives, what passion could motivate us to do what is right? Third, in what, if anything, does choice and free will - moral agency - consist?

Locke's answer to the first question, already given in *Essays on the Law of Nature*, is that the concept of obligation comes with the relational concept of law: '*Morally good and evil* then, is only the conformity or disagreement of our voluntary actions to some law, whereby good or evil is drawn on us, from the will and power of the lawmaker; which good and evil, pleasure or pain, …is that we call *reward* and *punishment*' (*Essay* II.xxviii.5). Locke makes it clear that the notion of obligation presupposes the right, as well as the power of the lawgiver to legislate and punish - in *Essays* Locke's 'power' is explicitly *potestas*, authority, rather than *potentia*, mere force. There are, he says in the *Essay*, three kinds of law: divine law, the measure of sin and moral duty; civil law, the measure of crimes and innocence; and the law of opinion or reputation, the measure of virtue and vice. God legislates by *ius creationis*, the maker's right over what is made, and divine law is binding on all rational creatures capable of pleasure and pain. God's law accords with his wisdom and benevolence, so that we can know it by reflecting on what a wise and benevolent Deity would require of us. Unsurprisingly, Locke's ethics is heavily utilitarian.

The relationship between divine law and civil law, and the standing of the civil magistrate under divine law, is the subject-matter of Locke's political theory as expounded in *Two Treatises*. The notion of a 'law of reputation', sometimes called 'the philosophical law', has a more complex role in his thought. It is Locke's explanation of popular secular morality, but it also represents his view of the possibility of non-theistic philosophical systems of ethics. Roughly, the thought is that ordinary morality, sanctioned by public approval and disapproval, exists as a means to the preservation of society, itself a condition of the happiness of individuals. As arrangements differ between societies, so do their moral concepts and what counts as virtue and vice in each, although naturally there will be overlap given their shared aim of self-preservation. Since the divine law too is concerned with the good of human beings, and with self-preservation as a duty, the law of reputation will tend to coincide with divine law. In the aborted fragment of the *Essay*, 'Of Ethick in General', Locke suggests that philosophers may have some inkling of the divine law, but they confuse it with the law of reputation. Consequently their systems reduce either (like that of Hobbes) to an advocacy of what tends to the preservation of society, or (like that of Aristotle) to the elaboration of a set of definitions of the behaviour of which a particular society approves or disapproves (King [1829] 1864: 308-13). Locke does not deny the social importance of the law of reputation, however, and in *Some Thoughts concerning Education* he assigns a necessary role in a child's moral education to public esteem and

shame. His complaint is that an explanation of moral obligation in terms of the value of certain actions to society, and the value of society to the individual, cannot explain how we may be morally obliged to do something contrary to our own felt interest - our interest, at least, in this world. Self-interest may commonly prescribe adherence to social rules, but it may not always do so. As Locke says in the *Essays on the Law of Nature* ([1664] 1954: 204) 'a great number of virtues, and the best of them, consist only in this: that we do good to others at our own loss'.

Locke's position is, then, that in order to explain both moral obligation and moral motivation (conflated in the usual seventeenth-century notion of obligation), we need to see morality as a system of laws prescribed by a supremely rational, just and benevolent creator to whom we owe the duty of obedience as creatures, and whose power to reward and punish in the next life is capable of motivating anyone who duly considers it (see Voluntarism). Like any theistic explanation of morality's binding force, this proposal is incoherent, and in its case the incoherence lies in the combination of the view that obligation is created by law with the claim that we have a natural obligation to obey the law of our creator. Locke, however, was more exercised by the problem of why consideration of the afterlife so often fails to move theists to do their duty. Indeed, he accorded the problem wider scope, since he followed Pascal in the thought that the bare possibility of there being an afterlife, given the infinite good at stake, ought in reason to motivate the Christian life (see Pascal, B. §6). Locke's explanation of the human capacity to know the better and choose the worse involved a refinement of his theory of motivation which echoes his theory of error. In the first edition of the *Essay*, in the long chapter 'Of Power', he held that 'the choice of the will is everywhere determined by the greater apparent good' (*Essay* II.xxi.70). By the second, he believed that mere consideration of future benefit will not move us to action unless it gives rise to 'an *uneasiness* in the want of it' - that is, to desire. Only a present passion - and, it seems, a kind of pain - can move to present action. It may require some reflection on the situation, over and above the simple recognition of probable or possible consequences for good or ill, to bring desire up to scratch, and to 'suit the relish of our minds to the true intrinsic good or ill, that is in things'. Someone who sees the good but does not pursue it has not reflected enough: 'Morality, established upon its true foundations, cannot but determine the choice of any one that will but consider' (*Essay* II.xxi.70).

Locke's increased emphasis on the role of deliberation in his hedonistic theory of moral motivation complicates his much revised account of liberty. He adopted a self-determinist view of free will - a free action is not one that is causally undetermined, but one determined by the agent's 'own desire guided by his own judgement'. He defines 'liberty' as 'the power to act or not to act according as the mind directs' (*Essay* II.xxi.71). But another power became increasingly important to him, the power 'to stand still, open the eyes, look about, and take a view of the consequence of what we are going to do, as much as the weight of the matter requires' (*Essay* II.xxi.67), and it is in this power, he often suggests, that the liberty of rational agents really consists. The tension is unresolved, for Locke never retracts the rhetorical question to which he himself seems to have given an answer: 'For how can we think anyone freer than to have the power to do what he will?' (*Essay* II.xxi.21) (see Free will).

10 Political theory

Locke's mature political theory is set out in 'An Essay concerning the True Original, Extent, and End of Civil Government', the second of *Two Treatises of Government*, the first being a point-by-point rebuttal of Robert Filmer's biblically based patriarchalism (see Filmer, R.). Locke's primary contention is that the right to govern comes with a duty to govern in the interest of the governed. Failure by the government to recognize or observe this duty creates the right to rebel. Like the Natural Law theories of Hooker, Grotius and Pufendorf on which he draws, Locke's argument moves from first principles, in effect a fragment of his proposed demonstrative ethics; but much of its richness derives from links with his practical political concerns and interests. It presents attitudes and actions attributable to Charles II and James II as a betrayal of trust, hostile to those features of the British constitution most adapted to the essential purposes of government; but he also states principles relating to property, money, social conventions, taxation, punishment, family relations, inheritance, the rights of the poor, enclosure of land, the practice and justification of colonial settlement, and more.

Filmer had argued that both political authority and property rights exist only by divine institution - by God's giving Adam dominion over the creatures, by the subjection of Eve, and by Adam's natural paternal rights over his children. Monarchs are deemed natural inheritors of Adam's rights. A part of Locke's strategy, pursued in both Treatises, against this doctrine was to drive wedges between the possession and inheritance of property and the

possession and conveyance of authority, and between paternal (or, as Locke prefers, parental) authority and political authority. For example, the right of children to inherit their parents' property stems from their natural right (not just that of the eldest child) to sustenance by their parents, a right which cannot be supposed to embrace either patriarchal authority or political power. The analogy of power and property in Filmer's argument, however, was not only in relation to inheritance, for it entailed that individual ownership is simply a grant of use by the king, making taxation - its partial withdrawal - his personal right. Locke was therefore concerned to give property a quite different role in his explanation of political society.

For Locke, government is a human invention, to which personal property is prior. In a state of nature, he argues in the Second Treatise, human beings have an obligation, in accordance with divine or natural moral law, 'to preserve the rest of mankind', their equals as creatures and servants of God, by a rational extension of their duty to preserve themselves. More specifically, 'no one ought to harm another in his life, health, liberty or possessions' (*Two Treatises* II.6). Yet, before government, 'everyone has a right to punish the transgressors of that law to such a degree, as may hinder its violation'. The 'state of nature' is not, for Locke, a merely ideal abstraction, but a historical situation in which members of simple societies have lived and still live, unless in time of war, and in which independent national governments always necessarily exist. For international relations are not governed by positive law prescribed and sanctioned by constituted authority. In this situation the victim of aggression - or indeed any onlooker, for the violation is of the natural law which maintains the welfare of all - has the right to destroy the aggressor until offered peace, reparation and security for the future. Within civil society itself this 'right of war' or self-defence exists whenever the law cannot be effectively exercised, whether in the immediate circumstances of threatened harm, or when the administration of the law is manifestly corrupt, and itself employed to commit violence and injury.

'Liberty' in the state of nature is freedom from any constraint but the moral law of nature. Under government, it is freedom from the 'arbitrary will of another man', and from any human rule but the 'standing rule…common to everyone of that society'*Two Treatises* II.22). (Locke sees slavery as continuation of war - it is just if the war is just, when it is in lieu of capital punishment, the justly enslaved, like criminals, being 'outside civil society'. Yet this hardly stands as an endorsement of contemporary colonial slavery - indeed Locke denies that the children of aggressors can be justly enslaved, or even disinherited.) 'Possessions' arise in a state of nature with the act of appropriation which is a necessary condition of the use of any of the comestibles naturally available to all: 'this law of reason makes the deer, that Indian's who hath killed it' (*Two Treatises* II.30). Such appropriation is an extension of the principle that 'every man has a property in his own person', and therefore in 'the labour of his body'. Consequently whatever someone has 'mixed his labour with' is his, provided that it is for use, and 'there is enough, and as good left in common for others' (*Two Treatises* II.27). This principle applies also to the enclosure of land for agriculture, which vastly increases its productivity. With land, as in all else, 'labour makes the far greatest part of the value of things, we enjoy in this world' (*Two Treatises* II.42). Nevertheless, before the conventional use of money, no one would have either motive or right to produce more than they could use, give to others or exchange before it spoils. To take something from the common store and let it spoil is against natural law. Money, however, is an artifice which modifies the whole nature of property-rights, since it can be stored indefinitely without spoiling. Money makes it worthwhile to exploit land fully, and supplies a just means of keeping the product. So far from wronging others, enclosure and improvement greatly increase 'the common stock of mankind', making 'a day labourer in England' better off than a king among the (Native) Americans (*Two Treatises* II.41). Significant disparity of wealth becomes both possible and morally justified, on the assumption that none will suffer absolutely (in a Board of Trade paper Locke simply asumed that everyone should have 'meat, drink, clothing and firing…out of the stock of the kingdom, whether they work or no' - Bourne 1876 vol. II: 382). But the effect is greatly to complicate the administration of the law of nature, and to render its application uncertain, as well as to encourage its breach through greed.

All this, on top of the standing need for both impartiality and sufficient force to punish malefactors, necessitates government. The chief role of such government is to determine rules to order and preserve property. Common defence is another imperative. Government with such legislative and executive powers comes into existence when people, by consent, resign their 'executive power of the law of nature… to the public' (*Two Treatises* II.89). Each individual member gives consent, but is thereafter bound to move with the majority. To the objection that no such agreement has ever taken place, Locke argues that, although 'government is everywhere antecedent to records',

cases abound of new or primitive societies with elected leaders. In the first instance, this may be 'some one good and excellent man' or effective general, or indeed the father of a familial group, but experience of unrestrained monarchy encourages legislatures of 'collective bodies of men', with none above the law. In any case, consent is normally tacit, and given in the active enjoyment of the benefit of the law, whether by possession of land or 'barely travelling freely on the highway'. Such tacit consent obliges obedience to the law, although the obligation lasts only as long as the enjoyment, leaving the individual free to give up the benefit and 'incorporate himself into any other commonwealth'. Express consent, however, binds the individual to obey and assist a particular government until its dissolution (or breach of trust).

A subject's ultimate obligation is to the supreme power, which is the legislative, itself bound by the law of nature in its choice of means, 'established and promulgated laws', for the preservation of its subjects and their property. Given this role, a government has no right to tax its subjects without their consent 'either by themselves, or their representatives chosen for them'. In order to minimize the risk of the legislative acting in its own, rather than in the public interest, it is best that it be an assembly which meets from time to time, separate from the continuously acting executive. A third, 'federative' power of war, peace and alliances is less easily directed by antecedent laws than the executive power, but falls naturally into the same hands, since both depend on public force. Locke allows some qualification of the absolute separation of powers, and subordination of the executive to the legislative, in recognition of the 'prerogative' power of the English king to dissolve and convene Parliament as circumstances require, and to employ discretion in the execution of the laws (Locke notes without express approval the power to veto legislation). Yet Locke sees prerogative as justified only as falling under 'the power of doing public good without a rule' in the face of unforeseen circumstances, and as dangerously capable of abuse. Its continuous employment contrary to the public good, for example by refusing to convene the legislative or by tampering with the rules for its election, makes the king himself a rebel and destroyer of the government, at war with his own subjects, returning them to a state of nature with a right to set up a new government.

11 Influence

Perhaps no modern philosopher has had a wider influence than Locke. His immediate achievement was, with Newton, to bring to an end the dominance within Europe of Cartesian science and philosophy, unseating the broadly Neoplatonic notion that mind and world share a common, divinely imposed structure, in favour of a modest, naturalistic conception of human capacities. Careful observation and systematic description are more valuable than the construction of hypotheses purportedly achieved by super-experiential means. Locke's own 'historical' treatment of the mind as a familiar, describable but deeply mysterious part of nature had considerable influence on European thought. His theory of classification influenced later taxonomy, and his brilliantly original theory of personal identity is still a standard text for philosophical discussion. His philosophy was one of the chief influences on Kant, but can still suggest an alternative to Neo-Kantian conceptualism. If his ethical theory appears to be the last throes of early modern natural law theory rather than a new beginning, within that structure he enunciated a classic justification of responsible, tolerant and broadly democratic political society which has remained a major resource for political theorists ever since.

MICHAEL AYERS

List of works

Locke, J. (1823) *The Works of John Locke*, London: T. Tegg *et al.*, 11th edn, 10 vols; repr. Aalen: Scientia, 1963. (Still, in 1997, the most complete edition of Locke's works, together with some of the more philosophically interesting correspondence.)

Locke, J. (1975-) *The Clarendon Edition of the Works of John Locke*, general eds P.H. Nidditch (to 1983), J.W. Yolton (1983-92), M.A. Stewart (1992-), Oxford: Oxford University Press.(A critical edition, planned to include all the published works and significant manuscript material, the bulk of which is in the Bodleian Library, Oxford. Volumes are available or in active preparation in 1997 as indicated under individual titles below.)

Locke, J. (*c*.1660-2a) *Two Tracts on Government*, ed. P. Abrams, Cambridge: Cambridge University Press, 1967. (Useful introduction and notes. The 'tracts', the first in English, the second in Latin, debate 'Whether the Civil Magistrate may lawfully impose and determine the use of indifferent things in reference to Religious

Worship?' Contrary to his later stance, Locke argues in these early manuscripts for the right of the magistrate to regulate religious observance for the sake of public peace.)

(*c*.1660-2b) 'An necesse sit dari in Ecclesia infallibilem Sacro Sanctae Scripturae interpretem?' (Is it necessary to have in the Church an infallible interpreter of Holy Scripture?), ed. J.C. Biddle in 'John Locke's Essay on Infallibility: Introduction, Text, and Translation', *Journal of Church and State* 19 (1977): 301-27.(A critique of the notion of infallibility.)

Locke, J. (1664) *Essays on the Law of Nature*, ed. and trans. W. von Leyden, Oxford: Oxford University Press, 1954; ed. and trans. R. Horwitz, J. Strauss Clay and D. Clay as *Questions concerning the Law of Nature*, Ithaca, NY: Cornell University Press, 1990.(An early manuscript in Latin in scholastic form which, despite later change in Locke's conception of moral knowledge, throws light on his mature moral theory as well as the development of his thought. Von Leyden's edition includes related manuscript material.)

Locke, J. (1667) *An Essay concerning Toleration, in John Locke: Writings on Politics, Law and Religious Toleration 1667-1683*, ed. J.R. Milton and P. Milton, Clarendon Edition, Oxford: Oxford University Press, forthcoming.(This manuscript signals Locke's change of mind to a more liberal view of religious toleration.)

(?) (*c*.1668) 'De Arte Medica', in H.R.F. Bourne *The Life of John Locke*, 2 vols, London: Henry S. King, 1876, vol.1, 222-7; repr. in K. Dewhurst *Dr Thomas Sydenham (1624-1689): His Life and Original Writings*, London: Wellcome Historical Medical Library, 1966.(A manuscript in Locke's handwriting, but possibly by Sydenham, expounding a strongly empirical method in medicine.)

(?) (1671) *Drafts for the Essay concerning Human Understanding, and Other Philosophical Writings*, vol. 1, ed. P.H. Nidditch and G.A.J. Rogers, Clarendon Edition, Oxford: Oxford University Press, 1990-.(Volume I contains *Drafts A and B* (1671); the forthcoming volumes II and III contain *Draft C* (1685) and associated manuscript material. Together they cast considerable light on the development and significance of Locke's general philosophy, including projected, but unfinished chapters of the *Essay*.)

Locke, J. and Tyrrell, J. (1681-3) *Locke on Separation*, ed. J. Marshall, Clarendon Edition, Oxford: Oxford University Press, forthcoming.(A jointly written, hitherto unpublished response to Edward Stillingfleet's *The Mischief of Separation* (1680) and *The Unreasonableness of Separation* (1681) in which Locke and Tyrrell defend toleration of religious nonconformity.)

Locke, J. (1686) 'Newton, Is. Philosophiae naturalis principia mathematica…' (Mathematical principles of natural philosophy), *Bibliothèque universelle et historique*.(Review, by an admiring layman, of Newton's *Principia*.)

Locke, J. (1688) 'Abrégé d'un ouvrage intitulé Essai philosophique touchant l'entendement', *Bibliothèque universelle et historique*; separately published as *Extrait d'un livre anglois… intitulé Essai philosophique concernant l'entendement…*, Amsterdam, 1688; trans. as 'An Extract of a Book, Entituled, A Philosophical Essay upon Human Understanding', in *The young-students-library, containing extracts and abridgements…*, London, 1692; in *Drafts for the Essay concerning Human Understanding, and Other Philosophical Writings*, vol. 3, ed. P.H. Nidditch and G.A.J. Rogers, Clarendon Edition, Oxford: Oxford University Press, 3 vols, 1990-.(Locke's effective abstract of *An Essay concerning Human Understanding*.)

Locke, J. (1689) *Epistola de Tolerantia*, Gouda; ed. R. Klibansky *Epistola de Tolerantia: A Letter on Toleration*, trans., intro. and notes J.W. Gough, Oxford: Oxford University Press, 1968; trans W. Popple as *A Letter concerning Toleration*, London, 1689, 2nd edn, 1690, ed. J. Tully, Indianapolis, IN: Hackett Publishing Company, 1983.(Locke's classic argument for religious toleration. Popple's vigorous translation is the one through which the work has chiefly been known to English-speakers.)

Locke, J. (1689/90a) *An Essay concerning Human Understanding*, ed. P.H. Nidditch, Clarendon Edition, Oxford: Oxford University Press, 1975.(Originally published in December 1689 but carrying the date 1690. Locke's chief and greatest work, arguing comprehensively that what we can think and know is limited by the way we experience the world, attacking dogmatic pretensions to grasp the essences of things, and affirming that 'reason must be our last judge and guide in everything', including morals and religion.)

Locke, J. (1689/90b) *Two Treatises of Government*, ed. P. Laslett, Cambridge: Cambridge University Press, 1960, 2nd edn, 1967; ed. I. Harris, with associated manuscript material, Clarendon Edition, Oxford: Oxford University Press, forthcoming.(In the First Treatise 'the False Principles and Foundation of Sir Robert Filmer and His Followers are Detected and Overthrown' - that is, the patriarchal theory of monarchy. The Second Treatise, 'an Essay concerning the True Original, Extent, and End of Civil-Government', is a major classic of political theory, arguing that government is morally, and should be constitutionally, answerable to the governed. Laslett's influential introduction stimulated continuing debate as to the immediate context and purposes of *Two Treatises*, and its relation to the rest of Locke's thought.)

Locke, J. (1690) *A Second Letter concerning Toleration*, London; repr. in *The Works of John Locke*, vol. 6, London, 11th edn, 1823.(Locke defends religious toleration, and his argument of *Epistola de Tolerantia*, in

response to Jonas Proast's *The Argument of the Letter concerning Toleration, Briefly Consider'd and Answer'd*.)

Locke, J. (1691/2) *Some Considerations of the Consequences of the Lowering of Interest, and raising the Value of Money*, in *Locke on Money*, ed. P.H. Kelly, Clarendon Edition, Oxford: Oxford University Press, 1991.(Advice on the coinage which became Government policy.)

Locke, J. (1692) *A Third Letter for Toleration, to the Author of the Third Letter concerning Toleration*, London; repr. in *The Works of John Locke*, vol. 6, London, 11th edn, 1823.(Continues the argument of *Epistola de Tolerantia* and *A Second Letter concerning Toleration*, against Jonas Proast).

Locke, J. (1693) *Some Thoughts concerning Education*, London; 3rd enlarged edn, London, 1695; ed. J.W. Yolton and J.S. Yolton, Clarendon Edition, Oxford: Oxford University Press, 1989.(Consciously modest in scope, but an important and interesting work in the history of educational theory.)

Locke, J. (1695a) *The Reasonableness of Christianity*, London; 2nd edn, 1696; ed. J. Higgins-Biddle, Clarendon Edition, Oxford: Oxford University Press, 1998.(Locke's latitudinarian credo, cutting articles of faith to a minimum and emphasising the moral dimension of Christianity.)

Locke, J. (1695b) *A Vindication of the Reasonableness of Christianity, etc. from Mr Edwards's Reflections*, London; repr. in *The Works of John Locke*, vol. 7, London, 11th edn, 1823.(The first of Locke's responses to John Edwards' attack on *The Reasonableness* in *Some Thoughts concerning the Several Causes and Occasions of Atheism, Especially in the Present Age*, 1695.)

Locke, J. (1697a) *A Second Vindication of the Reasonableness of Christianity,…*, London; in *The Works of John Locke*, vol. 7, London, 11th edn, 1823.(A reply to John Edwards' response to *A Vindication of the Reasonableness of Christianity*.)

Locke, J. (1697b) *A Letter to the Right Reverend Edward, Lord Bishop of Worcester, Concerning some Passages relating to Mr. Locke's Essay of humane Understanding: In a late Discourse of his Lordship's, in Vindication of the Trinity*, London; in *The Works of John Locke*, vol. 4, London, 11th edn, 1823; repr. in *The Locke-Stillingfleet Debate*, ed. M.A. Stewart, Clarendon Edition, Oxford: Oxford University Press, forthcoming.(Stimulated by the theological objections of Edward Stillingfleet, Bishop of Worcester, Locke explains in particular, in this *Letter* and two further *Replies* (1697/1699), his theories of substance, real and nominal essence, and personal identity, and his agnostic attitude towards the issue between dualism and materialism. M.A. Stewart's edition will contain Stillingfleet's contributions to the debate.)

Locke, J. (1697c) *Mr Locke's Reply to the… Bishop of Worcester's Answer to his Letter…*, London; in *The Works of John Locke*, vol. 4, London, 11th edn, 1823; repr. in *The Locke-Stillingfleet Debate*, ed. M.A. Stewart, Clarendon Edition, Oxford: Oxford University press, forthcoming.(Continues the argument of *A Letter to the…Bishop of Worcester*.)

Locke, J. (*c*.1699) *The Elements of Natural Philosophy*, in *The Works of John Locke*, vol. 3, London, 11th edn, 1823.(An introductory survey of natural philosophy as Locke saw it, written for the son of his hosts, the Mashams.)

Locke, J. (1699) *Mr. Locke's Reply to the…Bishop of Worcester's Answer to his Second Letter…*, in *The Works of John Locke*, vol. 4, London, 11th edn, 1823; in *The Locke-Stillingfleet Debate*, ed. M.A. Stewart, Clarendon Edition, Oxford: Oxford University press, forthcoming.(Continues the argument of *A Letter to the…Bishop of Worcester, and Mr Locke's Reply….*)

Locke, J. (1700-4) *A Paraphrase and Notes on the Epistles of St Paul*, London, 6 vols, 1705-7; ed. A.W. Wainwright, Clarendon Edition, Oxford: Oxford University Press, 2 vols, 1987.(Locke's chief contribution to biblical hermeneutics, now published with associated manuscript material.)

Locke, J. (1702) *A Discourse of Miracles*, in *The Works of John Locke*, vol. 9, London, 11th edn, 1823.(Defines miracles as divinely purposive and contrary to common experience, but not as contrary to the unknown laws of nature).

Locke, J. (1704) *Fourth Letter on Toleration*, in *The Works of John Locke*, vol. 6, London, 11th edn, 1823. (Locke's last, unfinished shot, following those of 1690 and 1692, in defence of the position taken in *Epistola de Tolerantia* against Jonas Proast.)

Locke, J. (1976-) *The Correspondence of John Locke*, ed. E.S. de Beer, Clarendon Edition, Oxford: Oxford University Press, 8 vols, plus forthcoming index.(Around 3,650 letters from and to Locke in the period 1652-1704 supply important evidence of his life and times. A number of exchanges, for example, those with Molyneux and Limborch, are philosophically important.)

Locke, J. (1991) *Locke on Money*, ed. P.H. Kelly, Clarendon Edition, Oxford: Oxford University Press, 2 vols. (Contains all Locke's writings on economics (1668-95), with a long introduction explaining their significance.)

Locke, J. (forthcoming) *John Locke: Writings on Politics, Law and Religious Toleration 1667-1683*, ed. J.R.

Milton and P. Milton, Clarendon Edition, Oxford: Oxford University Press.(Contains the 1667 ‘Essay concerning Toleration’ and other manuscript writings from this crucial period of Locke’s association with Shaftesbury.)

Locke, J. (forthcoming) *The Journals of John Locke*, ed. H.A.S. Schankula, Clarendon Edition, Oxford: Oxford University Press, 4 vols.(Important evidence of Locke’s life, interests, reading and the development of his thought, 1675-1704. Some philosophically significant entries were previously published in *An Early Draft of Locke’s Essay*, ed. J.I. Aaron and J. Gibb, Oxford: Oxford University Press, 1936.)

References and further reading

Aaron, R. (1937) *John Locke*, Oxford: Oxford University Press, 3rd edn, 1971.(For long one of the two standard commentaries on the *Essay*, differing from Gibson (1917) in several important respects, some, but not all, improvements.)

Alexander, P. (1985) *Ideas, Qualities and Corpuscles: Locke and Boyle on the External World*, Cambridge: Cambridge University Press.(An extended consideration of the version of corpuscularianism favoured by Locke, and of its bearing on his epistemology and metaphysics.)

Ashcraft, R. (1986) *Revolutionary Politics and Locke’s Two Treatises of Government*, Princeton, NJ: Princeton University Press.(Makes strong, controversial claims about Locke’s active engagement in revolutionary politics during the writing of the *Two Treatises*.)

Ashcraft, R. (1987) *Locke’s Two Treatises of Government*, London: Unwin & Hyman, 1987.(An important analysis of the arguments of *Two Treatises*.)

Ashcraft, R. (ed.) (1991) *John Locke: Critical Assessments*, London: Routledge, 4 vols.(A large selective collection of some of the more significant articles written on Locke’s thought, a volume each on political theory, general philosophy, education and economics.)

Attig, J.C. (1985) *The Works of John Locke: a comprehensive bibliography from the seventeenth century to the present*, Westport, CT and London: Greenwood.(A list of editions and translations, including abridgements and selections, of Locke’s writings, together with other works, antecedent and precedent, constituting the immediate controversial context. Secondary works are cited in relation to publication details.)

Ayers, M. (1991) *Locke*, London: Routledge, 2 vols; repr. in 1 vol. as *Locke: Epistemology and Ontology*, London: Routledge, 1993.(The most comprehensive commentary on the *Essay*, interpreting and assessing Locke’s arguments in their intellectual context, but also offering detailed argument with respect to their continuing philosophical significance.)

Bourne, H.R. Fox (1876) *The Life of John Locke*, London: Henry S. King, 2 vols.(An important biography, but now largely outdated. Bourne made use of available documents, but lacked direct access to the manuscripts now in the Lovelace Collection in the Bodleian Library.)

Chappell, V. (ed.) (1994) *The Cambridge Companion to Locke*, Cambridge: Cambridge University Press.(A well-organized and useful collection of specially written articles covering Locke’s main philosophical concerns, with a good selective bibliography.)

Christophersen, H.O. (1930) *A Bibliographical Introduction to the Study of John Locke*, Oslo: Jacob Dybwad; repr. New York: Burt Franklin, 1968.(A pioneering, incomplete bibliography.)

Colman, J. (1983) *John Locke’s Moral Philosophy*, Edinburgh: Edinburgh University Press.(A pioneering analysis of Locke’s ethical theory which is careful, judicious and comprehensive in its analysis of Locke’s arguments about ethics, but Colman’s view of their relation to Locke’s theology is open to question.)

Cranston, M. (1957) *John Locke: A Biography*, London: Longmans; repr. Oxford: Oxford University Press, 1985.(Based rather narrowly on Locke’s then-recently rediscovered correspondence and journals, this is a readable account of his life, but is inaccurate on many details and unhelpful on his intellectual development.)

Dunn, J. (1969) *The Political Thought of John Locke: An Historical Account of the Argument of The Two Treatises of Government*, Cambridge: Cambridge University Press.(A classic study, placing Locke’s political theory in its historical and intellectual context and revealing some of the coherence of his thought that had escaped earlier commentators.)

Edwards, J. (1695) *Some Thoughts concerning the Several Causes and Occasions of Atheism, Especially in the Present Age*, London.(Contains an attack on Locke’s *Reasonableness* which, together with further attacks in *Socinianism unmask’d* (1696), *The Socinian Creed* (1697), and *A brief vindication of the fundamental articles of the Christian faith…from Mr. Lock’s reflections upon them* (1697), stimulated Locke’s own *Vindication* (1695b), and *Second Vindication* (1697c).)

Gibson, J. (1917) *Locke’s Theory of Knowledge and its Historical Relations*, Cambridge: Cambridge University Press.(An intelligent, still useful commentary, despite important mistakes.)

Yolton, J.W. (1970) *Locke and the Compass of the Human Understanding*, London: Cambridge University Press. (An important contribution to the interpretation of Locke's philosophy of science and moral theory.)

Logic in China

Technically, classical China had semantic theory but no logic. Western historians, confusing logic and theory of language, used the term 'logicians' to describe those philosophers whom the Chinese called the 'name school'. The best known of these were Hui Shi (380-305 BC) and Gongsun Lung (b. 380 BC?). This group now also includes the Later Mohists and the term 'distinction school' (translated as 'dialecticians') has become common.

The importance of the more detailed Mohist work came to light in modern times. The Confucian tradition had lost access to it. Rescuing that text rekindled a long-lost interest in Chinese theories of language. The restored Mohist texts give us a general theory of how words work. A term picks out part of reality. Some terms are more general than others; terms like 'dobbin' or 'horse' or 'object' might pick out the same thing. When we use a term to pick something out, we commit ourselves to using the name to pick out similar things and 'stopping' with the dissimilar. Thus, for each term we learn an 'is this' and an 'is not'. 'Is not' generates an opposite for each name and marks the point of distinction or discrimination.

Chinese doctrine portrays disagreements as arising from different ways of making the distinctions that give rise to opposites. The word bian *(distinction/dispute) thus came to stand for a philosophical dispute. The Mohists argued that, in a 'distinction/dispute', one party will always be right. For any descriptive term, the thing in question will either be an 'is this' or an 'is not'.*

Mohists were realistic about descriptions and the world. Real similarities and differences underlie our language. They rejected the claim that words distort reality; to regard all language as 'perverse', they noted, was 'perverse'. The Mohists failed, however, to give a good account of what similarities and differences should count in making a distinction. Mohists also found that combining terms was semantically fickle. In the simplest case, the compound picked out the sum of what the individual terms did. Classical Chinese lacked pluralization so 'cat-dog' works like 'cats and dogs'. Other compound terms (such as 'white horse') worked as they do in English. The confusion led Gongsun Long to argue, on Confucian grounds, that we could say 'white horse is not *horse'.*

Confucius' linguistics centred on his proposal to 'rectify names'. Confucius used a code with fixed formulations, and therefore tended to treat moral problems as turning on which terms we use in stating them. The abortion dispute illustrates this well. Both sides agree to the rule 'do not kill an innocent *person': the dispute becomes one of whether to use the term 'person' or 'foetus'. In contrast, Mohists argued that we should not alter normal term use to get moral results. We simply accept that guiding compounds may not follow normal use. A thief is a person, but killing a thief (executing) is not killing a person (murdering).*

These results bolstered Daoist scepticism about words. We never will fashion a 'constant' dao. According to Zhuangzi, even a realistic theory of language (like that of the Mohists) will not give constant guidance. He drew from Hui Shi's approach to language, which emphasized relative terms such as 'large' and 'small'. We may talk of a large horse (relative to other horses) or a large horsefly (relative to other flies), but 'large' itself has no constant standard of comparison. From the premise, 'all such distinctions are relative', Hui Shi fallaciously concluded that 'reality has no distinctions in itself'. Zhuangzi rejected this conclusion and ridiculed Hui Shi's monism. If we say 'everything is one', then our language attempts to 'point to' everything. If it succeeds, then in addition to the 'one-everything' there is the reference to it. That makes two. The whole consisting of everything and saying so then makes three. Referring to that whole makes four, and the fact that we have referred to it makes five, and so on.

Zhuangzi shifted Hui Shi's focus slightly, and concentrated on 'this' and 'that'. These do refer to things, but each use is different. Language, he argued, is not fixed on the world but on our relationships with it. Each existing language (different ways of making guiding distinctions) is equally natural. Human debate is as natural as the chirping of birds. We cannot appeal to nature to settle our disputes about ethics. The standards are not constant; they are historical, variable and diverse in different moral communities.

Distinctions are real, but we can never know if we have found the right ones. Zhuangzi accepts a real world in which language works. Thus, he celebrates the endless possible ways of distinguishing 'this' from 'not-this'. Some alternatives will certainly work better (assuming our present values) than the one we have now. The problem is

that any standard we could use to decide about that would itself be controversial.

The final word came from Xunzi and his student Han Feizi. The former, a Confucian, understood Zhuangzi's arguments to show that the only standard of correct usage must be convention itself. Thus he renewed Confucian tradition and promoted it politically as the only viable and valid conventional system. He advocated government suppression of dissenting voices who 'confuse language' and 'create new terms'. In the end, only the ruler may change language (and then only the 'descriptive' terms). The standards of social assent and dissent come from the Confucian 'sage-kings'. We must adhere to these as the only acceptable ideals; the alternative is anarchy in moral discourse and, consequently, in society.

Han Feizi, seized on Xunzi's attitude toward coercion while discarding the appeal to ancient tradition. Han Feizi had considerable influence on the draconian Qin emperor who ruthlessly carried out his injunction to stamp out philosophical disputes about ethics. This brought the rich tradition of creative philosophy to an abrupt end; religious thought and scholasticism dominated the rest of Chinese intellectual history.

1 Confucius: rectifying names

To understand the development of theory of language, we must place it in the context of Chinese ethical thought. The central focus of ethical dispute was about *dao*, or 'guiding discourse' (see Confucian philosophy, Chinese §2). Confucius championed the historical 'guiding discourse' of the sage-kings, and purportedly studied it in the ancient documents that formed the curriculum of his school. The *Liji (Book of Rites)* is the paradigm for Confucius' conception of ethics.

Confucius' semantic framework was the relation between language and action, not between language and objects or reality. The implicit role of language was prescriptive rather than descriptive. Confucius, oblivious to ethical criticism of his discourse-based guide, addressed mainly problems in practical interpretation. His theory implied a pragmatic relation between language and objects. In order for a discourse to guide us, we must correctly pin names on the world's 'stuff'.

Confucius argued for imitation as the way to achieve this. Social leaders model the proper use of names in publicly practising the 'ritual'; the people learn from these examples and are then able to follow the code as it applies to them. Confucius called this 'rectifying names', and treated it as the key to good government:

> Zilu said, 'The ruler of Wei awaits your taking on administration. What would be Master's priority?' The Master replied, 'Certainly - rectifying names!' … If names are not rectified then language will not flow. If language does not flow, then affairs cannot be completed. If affairs are not completed, ritual and music will not flourish. If ritual and music do not flourish, punishments and penalties will miss their mark. When punishments and penalties miss their mark, people lack the wherewithal to control hand and foot. Hence a gentleman's words must be acceptable to vocalize and his language must be acceptable as action. A gentleman's language lacks anything that misleads - period.
>
> (*Analects* 13:3)

The strategy of setting examples threatens a regress unless someone in the chain of models knows what example to set in some other way. Stopping the regress pushes Confucianism toward intuitionism. Confucius seemed to regard a mysterious quality, *ren* (humanity), as the key to correct practical interpretation of the *li* (ritual). 'Humanity' is a moral insight that guides the attribution of terms in following circumstances.

One does not rectify by consulting definitions: no Chinese accounts of language generate or point to anything like the concept 'meaning'. The model of the language-world relation is political. Social authorities tag things for ethical purposes. This tagging facilitates guiding discourse. Two theories of Confucian tagging emerge: one determined by traditional training and one by innate moral intuition.

Classical Chinese grammar reflects this model of language-world relations in its topic-comment structure. In the place of sentences, literary Chinese makes 'comments' on contextually indexed 'stuff'. Classical sentences required no subject. Language appeared as far more context dependent than in modern Western thought, with its focus on the subject-predicate sentence and 'complete thought'.

Implicit cognitive theory also mirrored this topic-comment structure. Western philosophy focused on propositional

belief, a mental state that represents a fact, and knowledge. However, ancient Chinese grammar had neither propositional belief nor knowledge structures. Chinese grammar suggests a person tending to deem some real object (*X*) as *P* (the comment). Knowing is correctly deeming or assigning *P* to *X* (or knowing *X*'s being deemed *P*). Literary Chinese used adjectives, one-place verbs and even nouns as two-place predicates in situations where we would use propositional belief structures: one *P*'s some *X*. An alternative structure uses the Daoist concept of *wei* ('deem-act', the *wei* of *wuwei*, 'lack deeming action'). One, with regard to *X*, 'deems-acts' it *P*.

For these reasons (along with the absence of functional inflection, an ideographic conception of writing and the close grammatical similarity of proper and common nouns, adjectives and even verbs), Chinese linguistic theory focused on the question of what term to assign to things rather than on the propositional units so central to Western theory of language and logic (see Language, philosophy of). The dominant conception was that a word had a scope or range of application, rather than that of referring to individuals or objects. This tendency reflects the fact that Chinese nouns resemble mass-nouns in having cumulative reference, in lacking both grammatical number and articles, and in being associated with various ways of individuating. The use of sortals for individuation became regularized for Chinese nouns at the end of the classical period.

2 Mozi: language utilitarianism

The natural development of this model in Mozi's early work (and the subsequent elaboration in later Mohism) focuses on *bian* (distinction/dispute) (see Mohist philosophy; Mozi). A term's use involves an 'is this/right' (*shi*) and an 'is not this/wrong' (*fei*). To learn the term is to learn to 'is this/is not this' appropriately with it. Mozi argued that society should use the pre-conventional or natural 'will' toward benefit (and against harm). This contrast guides the assignment of 'is this/is not this' to words used in social discourse. This interpretive proposal flowed imperceptibly into a proposal to order guiding dialogues differently, to change Confucius' traditional 'guiding discourse'.

The clearest example is Mozi's argument about spirits and fate. General utility dictates that social discourse should include the string 'lack spirits' and 'have spirits'. He represents this conclusion as an example of knowing the *dao* of *you-wu* (have-lack) (see You-wu). That means making a 'is this/is not this' (*li-hai*) distinction for each of these terms using the standard of 'benefit-harm'. We use either 'have' or 'lack' of things when so doing will lead to general utility.

The implication was initially anti-realistic. Mozi advocated three standards of language use. The first recognized the historical, conventional aspect of language. Language should conform to the guidance intentions of the ancient sage-kings. Second, language standards should be applicable by ordinary people using their 'eyes and ears'. Mozi's favourite examples of *fa* (standards) are measurements: a plumb line, a compass, a square and stakes for plotting where the sun rises and sets (see Fa). Finally, we should use words in ways that maximize general utility. For Mozi, these standards pull in essentially the same direction. He assumed the people's good motivated the sage kings and he repeatedly likened the 'will of nature' to an objective utility measurement.

These standards govern the content and practice of discourse, regulations, injunctions, maxims and slogans. Including any string in the approved discourse was 'making it constant'. The ideal was a discourse *dao* that could consistently (reliably) and correctly (objectively) guide society. Mozi identified that *dao* as the one that resulted in the greatest utility for the country and its people. Thus, description or assignment of names is a handmaiden to ethics.

To count as the constant *dao*, Mozi's 'benefit harm' standard must itself be 'constant'; it should be a reliable, unambiguous and objectively correct, unchanging standard. He argued that in fact it was, since it came from *tian* (nature) rather than from society, convention or contingent history (see Tian).

Mozi's attack on conventional guiding discourse led Mencius to defend Confucianism by postulating an innate moral intuition. Mencius argued that language should not manipulate or guide human action. Guidance should only come from the innate patterns or dispositions in the heart-mind; these include an innate ability to 'is this/is not this' (see Xin (heart-and-mind)). The heart-mind selects the appropriate 'is this/is not this' assignment and thus the appropriate action in real contexts. Society should not distort or reshape those natural moral inclinations. Mencius believed that, left to itself, everyone's heart-mind would innately select the 'correct' action for them.

Laozi pointed in a similar direction but undermined Mencius' optimism. Indeed, we should resist the conventional socialization that comes with language. Learning names both constrains natural spontaneity and creates new and disruptive competitive desires. However, Laozi portrayed natural behaviour as being much more 'primitive' than did Mencius. The realm of social concern would extend no further than the local agrarian village. Laozi also emphasized the anti-language aspect of intuitive guidance more than did Mencius. He hinted that Mencius' idea that some particular moral values were intuitive or innate was a result of confusing the unconscious result of learning a guiding language with innate intuition. Learning names involves training in how to make distinctions and how to 'desire' with them. The names, distinctions, desires and actions are linked distortions of natural spontaneity. Laozi's conclusion is his opening line: no guidance in discourse form is constant (see Daoist philosophy §2).

3 Rediscovery of later Mohist theory

Before discussing the later Mohists, let us glance at the textual explanation of the loss and recovery of the Mohist Canons. The current 'best' textual theory says the Mohists wrote two 'Canons' (I and II). Each consisted of a series of short maxims; the first half of each Canon was written vertically across the top of a standard-sized book of bamboo strips, and the second half on the bottom. The terse analytic theorems were then keyed to another bamboo book containing longer explanations, examples or arguments for them. The second set of bamboo books was indexed by putting the first character of the claim alongside the first character of the explanation.

When scribes later copied each strip of the canons straight through, they turned this clever system into a puzzle. With no understanding of linguistic theory, they treated the whole corpus as a set of consecutive essays. Since classical Chinese had no punctuation or grammatical inflection, this textual disaster obscured the slogans, jumbled the order and shrouded the indexing principle. The scribes absorbed the indexing character as part of the text of the now orphaned explications.

Given the philosophical sophistication and difficulty of the text, the Mohist school's obliteration at the beginning of China's philosophical Dark Age (roughly 200 BC-1000 AD) and the placement of the Canons in the middle of the most vociferous anti-Confucian classical text, the medieval Confucian orthodoxy had little motivation to tackle the puzzle until the late Qing dynasty. Sun Yirang (1848-1908) found the essential clue to unzipping and analysing the content in a phrase in the middle which read, 'read these horizontally'. Other Chinese scholars tried different reconstructions and this work still goes on. Angus Graham's *Later Mohist Logic, Ethics and Science* first delivered a version of the reconstructed text to Western sinologists in 1978 (Graham 1978).

As his title suggests, Graham shared the common view that the subject matter was logic. He assumed Mohists intended the text as a deductively connected set of definitions and propositions. The statements, however, do not resemble definitions. Genus-species form is infrequent and the slogans fit into a theory of use, not of meaning. They are far from forming a deductive set. Still, Graham's assumption guided his reconstruction in ways that made the content accessible to analysis. Many problems and obscurities remain, but Graham's reconstruction reveals a systematic and reasonably coherent theory of language.

The maxims do deal with central philosophical concepts and, like Chinese dictionaries, frequently give lists of substitution characters or a range of examples. Some slogans are metaphors which the explications exploit; others are helpful ways of re-thinking and reflecting on a familiar concept. In addition to theory of language, intelligible sections of the Canon present fragments of epistemological, geometrical, optical and economic theory.

4 Later Mohists: names and distinctions

The School of Names was technically not a school (see Mohist philosophy §5). Traditional scholars gave the name to individual thinkers who analysed names in conflicting ways; their motivations reflect the differing trends in pre-analytic political thinking. The later Mohists developed Mozi's pragmatic, reality-based approach to naming. Gongsun Long defended the Confucian ideal of an unambiguous guiding scheme of names (the one produced by rectifying names). This principle, he presumed, dictated a goal of one-name-one-thing. Hui Shi raised sceptical problems designed to show that language 'constancy' across all situations was impossible (a Daoist conclusion).

The later Mohists spoke of four 'objects' of *zhi* (knowing): names, 'stuff', union and deeming-action (see Zhi). Mozi used an example that helps us fix the relevant concept of 'knowing'. Blind people can 'know-to' produce

utterances like ‘black like coal’ or ‘white as snow’ but cannot distinguish things when placed in front of them. They know names, but not ‘stuff’ or union. Thus they cannot use the names to guide their actions.

The Mohists, as we noted above, lacked a doctrine of ‘belief’. ‘Knowing union’ meant competently assigning terms and descriptions to objects. The Mohists accepted that ‘knowing names’ was conventional knowledge. They stressed, however, that we apply conventions to an external reality, known independently of language. The goal of knowledge remained practical guidance, not representation or picturing. Once conventionally attached to some reality, the inherent similarities and differences determined a term’s application. Conventions presuppose a world-guided way to mark distinctions. Mohists portray name-object relations mereologically: a name applies to a scattered reality determined by *tong-yi* (same-different).

The Mohist terms for ‘reference’ - *ju* (pick out) and *qu* (choose) - had a practical tone. A name picks out some ‘stuff’ from the background. Convention determines which similarities and differences mark the boundary between *shi* (‘is this’, what a name picks out) and *fei* (‘is not this’, what it excludes). In using a name, we commit ourselves to go to some real limit and then stop.

The Mohists argued against the one-name-one-reality principle of rectifying names. Names, the Mohists argued, could be very general (like ‘thing’ itself), or based on similarity classes (like ‘horse’) or applied to only one thing (like ‘John’). They saw no objection in principle to having overlapping scopes and even two names for the same thing (like ‘puppy’ and ‘dog’).

Elaboration and defence of this account of *bian* (distinction) led to complications. How should we expand the account to explain what a string of two *ming* (‘names’, characters) picks out? The model used was the string *niu-ma* (ox-horse). The Mohist took this to pick out a compound stuff, the sum of the range of the two component terms (‘draft animals’). They called the unit a *jian* (whole) and its parts *ti* (substantive parts). This analysis of compounds made them analogous to general terms. However, this treatment raised several questions. In what sense is a compound really two things? Could we not view anything as a compound of more basic stuffs? Is there any fundamental kind of ‘substantive part’?

These questions lead to another: are there any basic *tong-yi* (same-different)? The Mohists gave no clear answer. They noticed many senses in which things can be ‘same - different’; some realities might be different only in being called by different names. Being ‘two’ was necessarily differentiated even though called by one name. Realities could also be the same in the sense of being included in some compound object. Conversely, they could be different in not being included in some ‘substantial part’: they could be the same or different in being in the same place or not, and finally they could be same or different in belonging to the same *lei* (kind) (see Mohist philosophy §5).

However, the Mohists analysed *lei* in a loose way. Having that with which *tong* (same) was the criteria of being *tonglei* (same kind). Not having ‘same’ was the criteria of not being of a ‘kind’. Although they might initially have intended to limit ‘kind’ to natural kinds, the account generalized it to almost any similarity based grouping of stuffs. Thus the Mohists could refer to oxen and horses as the same ‘kind’. The only clear examples of not-‘kind’ are things so unlike they are not comparable. ‘Which is longer, wood or night?’ they suggest, is an unintelligible question because it compares two different ‘kinds’.

The looseness of this account of classifying buttressed the sceptic’s position (see §§8-9) that the world offered no reliable basis for fundamental distinctions. The Mohists seemed vaguely aware of the difficulty and did condemn *kuangju* (‘wild picking out’, where we use irrelevant ‘same’ or ‘different’ to classify or distinguish). They gave no account, however, of what marks a ‘wild’ or irrelevant way of grouping ‘stuff’.

5 Semantic paradoxes and compound terms

The central term of assessment in the Mohist study was *ke* (assertible). They used it in several related ways. An expression may be described as ‘assertible’ of some object. If this object is introduced by another term, then ‘assertible’ became a way of exploring semantic relations between terms (see Semantics). Mohists asked whether we can sometimes, always or never describe things picked out by term *X* as *Y*.

The analysis, although in terms of assertibility rather than truth, yielded a familiar and important conclusion against certain forms of relativism (see Relativism). The Mohists argued that in any dispute involving

'distinctions', there will be a 'winner'. If one disputant claimed it was ox and the other that it was not ox, one would be correct. When one disputant claimed the object was ox and the other that it was horse, they did not count that as a distinction dispute. This was merely a formal result, but the Mohists took it as confirming that the world, not conventions, determined the right designation. The winner is the one whose description *dang* (hit on) it.

Another result was a distant cousin of 'All sentences are false'. Unlike the classic liar paradox (see Semantic paradoxes and theories of truth), the universal sentence does have a consistent truth value: it is always false. The Mohist conceptual tools, however, lacked two concepts, namely 'sentence' and 'truth'. Instead they construct the following replacement: with regard to language, deeming it exhaustively inadmissible is inadmissible. They explain this result as arising from one's own language and suggest the proposer try harder to find acceptable words.

This result undermines the anti-language positions, notably those of Mencius and Laozi. It invalidates any claim that language distorts 'guidance'. Two similar results undermine different formulations of similar points. One version decries distinctions. To make a distinction is to regard something as 'is not this', and to say 'distinctions are wrong' is to make a distinction. The Mohists say, 'to *fei* "*fei*" is perverse' (that is, to say 'saying "wrong" is wrong' is wrong). To recommend making no distinctions is to make a distinction (between making and not-making) and thus the recommender violates his own recommendation. Similarly, the Mohists observe, to teach that teaching lacks use, lacks use.

The analysis of compound terms produced some of the most striking evidence of the different conceptual structure. The Mohists ask what was assertible of the things picked out by compound terms. One standard case was 'ox-horse'. The Mohists note that 'not-ox' is assertable of 'ox-horse' on the same grounds that 'ox' is. The explanation goes that part of ox-horse is non-ox, so 'non-ox' is 'assertible'. We can understand the idea by reflecting on another example. We may ask someone how many children they have by asking how many 'boys girls' they have. Suppose the answer is 'three'. Now we may ask how many are boys. The answer may come back, 'none'. This would be a case in which we could say 'their boy-girls are not boys'.

However, the Mohists seems to have something stronger in mind. Even if the answer was 'two girls and a boy', the Mohists would argue that it would be right to say that (some of) their boy-girls were non-boy. Thus the Mohist concludes that, although we cannot say ox is non-ox or horse is non-horse, we can say intelligibly that ox-horse is non-ox-non-horse. The Mohists explain this result as arising from the fact that ox-horse 'does not interpenetrate'. In any compound that is ox-horse, the minimal parts will be either ox or horse, but not both. They term it a 'separable' compound.

The contrast is hard-white. This is also a compound term but, in this case, the components are inseparable. Wherever you go in that which is appropriately called hard-white, you get both. This is the kind of compound term more familiar in Western languages, the intersection compound (see Language, philosophy of). The scope of the combined term is an intersection of the scopes of the two component terms. Ox-horse, by contrast, is a sum compound. The scope of the combined term is the union of the scopes of the two component terms.

The Mohists do not give us any rule for distinguishing intersection compounds from union compounds beyond the metaphysical feature of 'penetrating' or 'excluding'. They do not explicitly use the language of scope. They also characterize compounds as 'inseparable' and 'separable'. This curious result arises partly because they treat both nouns and adjectives as 'names'. Both pick out or distinguish one part of reality from the rest. This leaves us with the impression of arbitrariness in how names form compounds, which Mohists explain via metaphysical 'penetrability' or its opposite.

6 Phrase matching

Although the Mohists proposed a realist theory of reference, they embedded this in a further theory that we are guided by language. Thus the fourth object is knowing how to 'deem act'. The Mohists viewed the object of combining names as guiding action. Thus names pick out 'stuff', while strings or *ci* (phrases) convey intentions. This led them to analyse mainly ethical compounds. The other study, of 'ox-horse' and 'hard-white' compounds (see §5), construed them merely as complex names (though it gave no consistent principle for determining their conventional scope). In the long intact section of this text, the Mohists pursued a different analysis, one that can take a superficially logical form:

Premise: *X* is *Y* (white horse is horse)
Conclusion: *KX* is *KY* (ride white horse is ride horse)

They called this ‘matching phrases’, and argued that it was not reliable. Success would be as follows: whenever the version with simple terms was positive (an ‘is this’ phrase), then the parallel with compound terms should be positive (a *ran* (‘so’) phrase). Conversely, a negative base (*X* is not *Y*: a ‘not this’ phrase) should yield a negative result (*KX* is not *KY*: a ‘not so’ phrase).

The Mohists list the different kinds breakdowns:

- Sometimes an ‘is this’ yields a not-‘so’;
- Sometimes a ‘not this’ yields a ‘so’;
- Sometimes a reference is comprehensive and sometimes not;
- Sometimes one reference is ‘is this’ and another one is ‘not this’

The rest of the essay consists of examples that illustrate the respective outcomes.

Graham, drawing on a part-of-speech analysis of ‘is this’ (subject) and ‘so’ (verb), treated this chapter as evidence that the Mohists discovered the subject-predicate sentence. He translated the procedure as ‘matching sentences’ and treated it as a discussion of logical form. The first two models do rely on syntactic complexes (*X Y ke*) which resemble syllogistic premises, but the latter two do not.

Classical Chinese uses no articles and has no ‘is’ verb. Expressions ending with the particle *ye* (assert) mark descriptive uses of referring expressions (noun-phrases). This signals that one is applying a descriptive term to a contextually selected object, not using the term to pick out the object. Translators typically render such structures in English as ‘(*X*) is *Y*’. In Chinese comments, the topic term (the *X*) is optional. The comment functions the same when the string is simply ‘*Y* assert’ and context supplies the topic. The ‘assert’, in other words, does not link two terms, it links a term to an object.

The *shi-ran* (is this-so) analysis given by the Mohists does fit the examples in a way consistent with the topic-comment analysis. If, on the other hand, we focus on the examples as sentences and treat the pattern as a form of inference, then the Mohist analysis will resemble a kind of algebraic logic. However, consistent with a topic-comment analysis, it may be better to regard it as extending the analysis of the conventional semantic effects of combining ‘names’ to form ‘phrases’.

That the analysis rests on conventional semantics of terms rather than logic of sentences sheds a new light on how the examples work. The Mohists do not use the model to correct conventional reasoning errors; rather, they use what we would conventionally say to determine whether a result is a ‘so’ or a not-‘so’. The most thoroughly illustrated breakdowns are those where an ‘is this’ base produces a not-‘so’. The examples are:

- Someone’s parents are people; one’s serving one’s parents is not one’s serving the people;
- One’s younger brother is a handsome man; one’s loving one’s younger brother is not one’s loving a handsome man;
- A carriage is wood; riding a carriage is not riding wood;
- A boat is wood; entering a boat is not entering wood;
- Robbers are people; abounding in robbers is not abounding in people; lacking robbers is not lacking people.

The Mohists expand on the last example in a way that signals both the ethical importance of the analysis and the nature of the alleged breakdown in parallelism:

- Disliking the abundance of robbers is not disliking the abundance of people.
- Desiring to be without robbers is not desiring to be without people.
- Everyone would agree with these so they should not object if we say ‘robbers are people but killing robbers is not killing people’.

We guess, following Graham, that the Mohists are defending their inherited doctrine of universal love by arguing that it is consistent with the (presumed) practice in Mohist communities of executing thieves.

What the denial amounts to is that, even if naming is objectively constant and reliable, the use of names in descriptions of actions or intentions does not reliably take one from an ‘is this’ to a ‘so’. An execution is not murder. Loving a brother is morally required, loving a handsome man is (presumably) shameful. Serving one’s parents is one kind of duty and serving the people another. One does not fulfil the latter in merely doing the former.

What emerges is an alternative strategy for dealing with the problem that Confucius addressed via rectifying names (see §1). The Mohists resist the implication that in executing thieves they must deny that thieves are people. They deny instead that executing thieves is murdering people. Rectifying takes place at the ‘phrase’ or ‘so’ level rather than at the ‘name’ level.

The next set of examples illustrate the converse case, those where we start with a ‘not this’ base and the result is a ‘so’:

- To read books is not books; to like reading book is to like book.
- Cockfights are not cocks; to like cockfights is to like cocks.
- About to fall in a well is not falling in a well. To stop one about to fall in a well is to stop one falling in a well.

This time the Mohists are expanding on fatalism: ‘That there is fate is not fated; to deny that there is fate is to deny fate’. It is harder to reconstruct a problem that is plausibly solved by this analysis.

The algebraic form is abandoned in illustrating the next two breakdowns in parallelism. The first is ‘part comprehensive; part not’:

- ‘Loving people’ depends on comprehensively loving people. ‘Not loving people’ does not.
- ‘Rides horses’ does not depend on comprehensively riding horses. To have ridden on horses is enough to count as riding horses.

These examples highlight the mass-substantive structure of reasoning about reference. In one phrase the term-reference is implicitly comprehensive, in the other it is not.

Finally, we come to the examples of one ‘is this’ and one is ‘not this’:

- Fruit of a peach is a peach, fruit of a bramble is not a bramble.
- Asking about a person’s illness is asking about the person. Disliking the person’s illness is not disliking the person.
- A person’s ghost is not the person. Your brother’s ghost is your brother. Offering to a ghost is not offering to a person. Offering to your brother’s ghost is offering to your brother.
- If the indicated horse’s eyes are blind, then we call the horse blind. The horses eyes are large yet we do not call the horse large.
- If the indicated oxen’s hairs are brown, then we call the oxen brown. The indicated oxen’s hairs are many yet we do not call the oxen many.
- One horse is horse; two horses are horse. Saying ‘horses are four footed things’ is a case of one horse and four feet, not a pair of horses and four feet. Saying ‘horses are partly white’ is two horses and some white, not one horse and partly white.

There is no further analysis or summing up. The moral, we assume, is a negative one. Had we treated the first algebraic model as a kind of logic, the Mohists’ argument by example would still show that it was invalid; it is not a reliable form in the sense that a true premise formally guarantees a true conclusion. However, the essay is not about sentences and truth at all. It is about whether there are reliable parallels developing from terms to longer (guiding) phrases.

The implicit answer is ‘no’. The Mohists offer no constant or consistent principles guiding the construction of longer ‘phrases’ out of terms even when the terms are consistently applied to external realities. They offer no way to systematically rationalize the conventional patterns of use. They retreat implicitly from Mozi’s goal of replacing convention with a constant *dao* (guide). If there is such a ‘guide’, then it is not a product of any simple projection from term reference. Moral guidance cannot derive from knowledge of natural kinds; it requires conventional,

creative human social activity. Dialectically, the negative result gives ammunition to the Daoists who argue that no constant ‘guide’ exists (see Daoist philosophy §2).

7 Gongsun Long: one name, one thing

Against the Mohist background, we can now make some sense of the previously obscure writings of Gongsun Long. The text that bears his name consists of a few dialogues. Each is introduced by a counterintuitive paradox followed by a discussion or chain of reasoning. Graham argued that at least two of these were forged out of misunderstood fragments of the Mohist writings. They apparently copied the phrases after the Canons had been zipped together and the indexing characters mixed into the text.

Two of the remaining dialogues: ‘White Horse’ and ‘Referring and Things’, serve as useful examples. They pose difficult puzzles, to which scholars have offered speculative, controversial and mutually inconsistent interpretations. The various interpretations flow partly from different principles used in selecting interpretive theories or ‘translation manuals’. A couple of interpretations are given here, serving both to illustrate that point and to allow us to locate and discuss alternative views of Gongsun Long’s theory.

In a (perhaps spurious) preface to the dialogues, Gongsun Long explains his motivation. He cites an example of Confucius rectifying names (see §1) and alleges that he is defending that view. Confucians mostly reject the affiliation, but it makes formal sense. If rectifying is to remove ambiguity from guidance, then it requires that only one name in a guidance situation can refer to the object. I either regard the male before me as ‘father’ or as ‘ruler’ or as ‘person’. Supposing he is all three, if I am to extract guidance from codified rules, I must decide which rule to use. That means deciding which term is relevant to this action situation. The Mohist attack on that policy rejected any one-name-one-thing principle.

The Mohist account of compounding had negative implications from this point of view. Separable or sum compounds, such as ‘ox-horse’, conform to the one-name-one-thing principle. The scope of each term remains constant when we combine the terms. The combination names a sum of the two. Hard-white compounding, by contrast, violates the principle of strict clarity and consistency in naming. The scopes change when we compound the terms.

Other sources record Gongsun Long as defending two theses: ‘separating the inseparable’ and ‘separating hard-white’. Since Graham argued that the dialogue on ‘Hard-White’ was forged, we cannot rely on it for an explanation. Still, we can confidently interpret the slogan since ‘hard-white’ is the Mohist example of an ‘inseparable’ or ‘interpenetrating’ compound. To ‘separate’ them would be to treat them as ‘excluding each other’ and the compound as a sum compound. Gongsun Long thus objects to the hard-white model.

The phrase ‘white horse’ selects one term from each type of compound. The White Horse dialogue begins with a question in the canonical analytic form: ‘Is "white horse not horse" assertible?’ followed by the answer, ‘assertible’. The rest is generally agreed to be a discussion between the sophist defending the answer and an ‘other’ who raises objections. The first defence is that ‘white’ names a colour and ‘horse’ names a shape. Shape and colour are different, so a combination of shape and colour is not merely a shape.

The other most cited argument is ‘if you ask for a horse, both a black or yellow horse can arrive. If you ask for a white horse, a black horse or yellow horse will not arrive.’ This illustrates an argument thread that ‘*X* is not *Y*’ follows from ‘*X* is different or distinguishable from *Y*’. The linking theme is that ‘white horse’ is a combination of two things and this requires that ‘white horse not horse’ be ‘assertible’. A Mohist might respond that ‘asking for a white horse’ is indeed different from ‘asking for a horse’, but a white horse is still a horse.

One line of interpretation treats the term ‘horse’ as referring to the abstract object ‘horseness’, and thus ‘white horse’ to ‘white-horseness’. The opening sentence thus states the *true* proposition that the two abstract concepts are distinct entities. Since the connected terms are logically singular, the ‘not this’ represents ‘non-identity’. This line of interpretation is motivated by the principle of charity and undermined by the principle of humanity. It makes the puzzling sentence true (by Western lights) but does not explain how the sophist would have had access to the concepts involved. It does not apply to the two terms when used in the supporting arguments, all of which refer to concrete horses.

An alternative interpretation, that ‘horse’ refers to horse-stuff, can exploit the ‘distinct-hence-different’ line of

argument and still consistently interpret the concrete references in the rest of the dialogue. If we similarly regard white as the mass-substantive - white stuff - rather than the abstract 'whiteness', we can see a connection to the Mohist theory of compound names. Gongsun Long regards 'intersection' or 'interpenetrating' compounds as contrary to the one-name-one-thing principle. If white horse consists of two names, each should consistently name (scattered) things. Used in combination, their 'naming' should remain consistent. Thus, they should name the sum of the two stuffs and, as in the case of 'ox-horse', 'not-horse' would be assertable of it.

Alternatively, we may either deny that 'white horse' consists of two names or that they are the same names as when used separately. 'White horse' must be thought of as having no essential relation to 'horse' but as a *sui generis* term for a new stuff. We might then say 'white horse is horse' is not analytically true. Its truth is an accident of usage which *could have been otherwise*. Thus, 'white horse not horse' is assertible.

Gongsun Long's argument then becomes a dilemma. Either we regard 'white-horse' as a sum-compound term - in which case the 'ox-horse' result follows - or we regard it as a *sui generis* non-compound name - in which case the conventions of its use could tie it to anything at all; it need not necessarily be horse. The assumption must be that a name is the same only if it has the same scope (names the same thing). Since 'horse' in 'white horse' does not have that scope it is not the same name and its use in the compound constitutes an arbitrary new term.

The other dialogue poses, if possible, even more daunting barriers to interpretation. The first sentence seems to be an explicit contradiction: everything under heaven is *zhi* (pointing), and yet 'pointing' is not 'pointing'. The rest of the dialogue is content-thin and teeters repeatedly on the edge of pure syntactic contradiction. The only nouns are the puzzling *zhi* (pointing) along with *wu* (thing-kind) and *tianxia* (the world). Most interpreters take the issue to be the meaning of 'pointing' (a rare, mild consensus), and most treat it as semantic reference or meaning.

There are reasons for worry: as we saw, the Mohists focused on 'picking out' 'stuff' from its surroundings. There is no evidence of the semantic concept of 'meaning'; 'reference' is a more plausible evolution of that theory. Using 'meaning,' however, makes this dialogue mesh better with the abstract interpretation of the 'White Horse' thesis. Otherwise, it is hard to find any evidence of a sense-reference distinction or find any indication that it is individual objects rather than mereological wholes or types that we 'point to' (see Sense and reference; Mereology).

One speculative interpretation exploiting the 'reference' interpretation is both philosophically interesting and relevant to issues that emerge in theory of language and metaphysics. Graham treats the crucial first phrase as meaning that although one can refer to each thing, one cannot refer to 'everything' because in that reference one does not refer to one's own act of referring. Zhuangzi later makes a similar argument against assertions of absolute monism: to say everything is one is to have the one and the saying, which makes two. Tempting as it is, the interpretation has little theoretical connection to the White-Horse thesis. Graham treats both dialogues as dealing with the principle that whole is different from the part. The principle in question needs both careful formulation and plausible motivation.

8 Hui Shi: relativism and monism

We have even less direct textual evidence of the philosophical views of Hui Shi. All that remains are ten paradoxical sayings recorded in the *Zhuangzi* and some stories of his playing as Zhuangzi's 'debating companion'. Still, we can be confident of his position because plausible motivations for the sayings are more intuitive and are plausibly reflected in Zhuangzi's Daoism (see Zhuangzi).

Hui Shi focuses on such distinctions as large/small, thick/thin, high/low, south/north and today/yesterday. The common feature is the variability in which term from each pair we can assert of some object. Most of his paradoxes make sense as contrary comments about the same thing, made from different points of view, such as these examples from *Zhuangzi* 33:

- Heaven is as low as the earth; mountains are level with marshes.
- The sun from one perspective is in the middle from another declining.
- Natural kinds are from one perspective living and from one dying.
- I go to Yue today and arrive yesterday.

The most important one for theory of language purpose strikes at the Achilles heel of Mohist realism, the

construction of similarity classes:

• The ten thousand thing-kinds are ultimately alike and ultimately different. This is called the great similarity-difference.

As the *Zhuangzi* develops this insight, it suggests that we can find a difference between any two things no matter how alike, and a similarity between any two things no matter how different. So, even if there are objective similarities and differences, they do not justify any particular way of distinguishing between thing kinds. For every category and name, we could have had conventions that just as consistently and with equal 'world-guidedness' divide things differently.

However, the list of Hui Shi's sayings begins and ends with seeming absolutes. He seems to take a classic, so-called Daoist metaphysical view of an undifferentiated single totality:

• The ultimately great which has nothing outside it - call it the Great One!
• The ultimately small has nothing inside it - call it the Small One!
• Universally love the ten thousand thing-kinds; the cosmos is one 'substantive part'.

The concluding statement echoes the Mohists' ethical doctrine and one of their technical terms. We do not have Hui Shi's reasoning, but a plausible explanation is that normally taken by interpreters of Zhuangzi. It is the familiar inference of absolutism from relativism. If all distinctions are relative to some perspective, then we can conclude that reality has no distinctions. All distinctions are false: reality is an undifferentiated total one.

The *Zhuangzi* presentation of Hui Shi's views notes: 'He had many perspectives and his library would fill five carts, but his doctrine was self-contradictory and his language did not hit the target: the intent to make sense of things' (*Zhuangzi* 33). Zhuangzi presumably understood the incoherence of denying distinctions and, if we accept Graham's speculation about pointing and things, also the notion of an ultimate one - an 'everything' concept. Whether or not Gongsun Long rejected the inference, Zhuangzi clearly did. Zhuangzi almost paraphrases Hui Shi:

> 'The cosmos and I were born together, the ten-thousand things and I are one.' Now, having already constructed a 'one' is it possible to say something about it? Having already called it a 'one' can we fail to say something about it? 'One' and saying it make two. Two and one make three and going from here, even a skilled calculator can't keep up with us, let alone an ordinary man.
>
> (*Zhuangzi* 2)

Zhuangzi displays an immense fondness for Hui Shi alongside a dismissive, almost belittling attitude toward the result of his 'distinction-dispute'. Traditional accounts have reckoned this as a mystic's haughty disdain for logic. However, when we grasp that Hui Shi's doctrines have nothing to do with logic and everything to do with theory of language, a different view of the dynamic emerges. It pairs an erudite, enthusiastic and loquacious but somewhat wooly-minded semantic dilettante (Hui Shi) and a language theorist *par excellence* (Zhuangzi). This is not a case of mysticism versus logic, it is a case of clear versus befuddled theory of language. Zhuangzi enjoyed debating with Hui Shi because he was one of the few with enough learning to be worth refuting, even though he was a relatively easy target for a dialectician of Zhuangzi's calibre.

9 Zhuangzi: Sceptical perspectivalism

Zhuangzi develops perspectivalism in a more consistent direction. He does not reject language (as perhaps Laozi did). Naturalism, taking the point of view of 'nature', does not require abandoning language. Human language, from the empty greetings and small talk to the disputes of philosophers, is another natural 'noise'. We are all 'pipes of nature' (*Zhuangzi* 2).

Zhuangzi grants the Mohist point that language has 'aboutness': 'Language is not blowing breath; there is language for language. That which it languages, however, is radically underdetermined' (*Zhuangzi* 2). He develops this claim with the aid of Hui Shi's relativism and his own analysis of the indexicality of all distinctions, and starts by asking to what does 'this' or 'that' refer? Is there anything that cannot be a 'this' or a 'that'? These terms do not have a rigid, naming relation to an external reality; they trace our changing relations to the realities. Zhuangzi's perspectival pluralism is not a version of Western subjectivity. He does not assign any special

perspective to the individual consciousness or internal representations. The kinds of perspective Zhuangzi discusses range from the ways people who speak different languages or accept different moral theories constitute a perspective. At the other extreme, each of us takes different perspectives at different times in our lives - or for that matter, different times of the day.

The Mohists' *ke* (assertible) is also relative to perspective, the changing conventions of usage and principles within disputing factions and schools. Any language that actually is spoken is 'assertible'. Zhuangzi says the appearance of right and wrong in language is a function of elaboration and embellishment of a way of speaking. So the disputes between Mohists and Confucians amount to different elaborated ways of assigning 'is this' and 'not this'.

Zhuangzi calls his 'perspective' on the relativity of language *ming* (clarity). It is a perspective from which we can project backward to an 'axis' of linguistic guidance systems. From that 'axis' there would be no limit to what could be treated as 'is this' or 'not this'; a *dao* (guide) is merely the path one takes from that axis. Thing-kinds are made so by our classifications.

Lacking any limit on possible systems of naming and guiding, we lack any limit on know-how. No matter how much we advance and promote a way of dealing with things, there are things at which we will be deficient. To have any developed perspective is to leave something out. This, however, is not a reason to avoid language and a perspective; it is simply the inevitable result of limitless knowledge and limited lives.

'Sages' project their perspectives and prejudices on 'nature' and 'those who have arrived' know to deem everything as one. Zhuangzi does not recommend we use that attitude. Instead of trying to transcend and abandon the usual or conventional ways of speaking, we should treat them as useful. They enable us to communicate and get things done. That is all it is intelligible to ask of them.

Beyond the usefulness of our language, we don't know the way things are in themselves. We may dub our lack of that metaphysical knowledge as *dao*. To tax our minds by trying to treat everything as 'one' differs from that admission of ignorance only in the emotion that accompanies it. In the end, neither scepticism nor monistic mysticism allows us to say anything about ultimate reality. They merely exhibit different attitudes towards saying… nothing.

10 Xunzi: Confucian conventionalism

The final chapter in Chinese language theory comes in the 'Rectifying Names' chapter of the *Xunzi*. Xunzi focuses on language because he wants to reassert that 'ritual' is the only standard of correct behaviour. He rejected Mencian intuitionism and gleaned insights from Zhuangzi and the dialecticians. The apparent moral he drew was that, since reality cannot be a standard of language correctness, the default standard must be convention.

Appeal to the usage of the sage-kings determines correct name use. The correct account of that usage is a historical tradition, by which Xunzi means the judgment of Confucian scholar-gentlemen. Thus Confucianism is vindicated by the weakness Mozi had exposed. Xunzi then goes on to construct an explicitly conventionalist theory of language which carries political implications.

Xunzi introduced an important clarification. He distinguished between two kinds of 'distinctions': *gui-jian* (noble-base) and *tong-yi* (same-different). The former correspond roughly to value distinctions and the latter to empirical or descriptive distinctions. The latter are the basis for interaction with other cultures, and a king is entitled to change these 'miscellaneous' terms. Even a king, however, cannot change conventional evaluative distinctions (ranks, titles, punishments or anything in the *li* (ritual)). For these we rely on the sage-kings' *dao* (guide) via the scholar-gentlemen's interpretation. Xunzi regards moral terms as conventional 'artifice' arising from thought, not from nature.

Political authorities rectify names for the original Confucian purposes (order and obedience). Xunzi treats the positions and paradoxes of the dialecticians solely in political terms. Philosophy of language causes social instability by undermining the public guiding language. Philosophers confuse the conventional relations of names and make 'is this/not this' unclear. This we must stop: we must have but one standard of terminology. The king, not disputing philosophers and warring schools, will govern introduction of new descriptive terms.

The king should keep three things in mind as he creates names:

(1) the reason for having names: the reason for having names is coordinating social behaviour and achieving social order. Hence, value terms govern how we assign descriptive terms.
(2) the basis of classifying as similar and different: we classify by taking the distinctions delivered by sense organs and using them according to the dictates of a heart imbued with the correct evaluative distinctions.
(3) the essentials of regulating names: the basis of regulating names is social order and the preservation of a stable, traditional scheme of language.

Xunzi's account of classifying similar and different takes a markedly empirical (epistemological) turn. Unlike the Mohists, Xunzi did not rely on claims that reality presented objective similarities and differences. Zhuangzi had argued that human standards of 'is this/not this' were no more natural than the opposing ones of other animals. Taking Zhuangzi's hint, Xunzi focused on human sense reactions to reality. Indeed, no neutral, inter-species ways of distinguishing things as similar and different exist. Still, while the senses of one species work differently from those of another, those of any one species makes similar distinctions.

All humans sense and respond to approximately the same range of natural distinctions (see Sense-data). The eyes of humans distinguish the same range and bands of colours, the mouth the same classifications of taste, the ears the same range and discriminations of pitch and so on. The shared nature of intra-species distinction-making underwrites the possibility of community and language. Thus, we abandon any appeal to cosmic nature and rely on what is pragmatically possible for humans in achieving natural human goals.

Our language conventionally clusters some sensible differences and ignores others. Historical, conventional standards dictate how it does this. These norms are transmitted into the cultured gentleman's heart when he masters the transmitted, sage-king's scheme of values. The heart rules the sense organs (as it did for Mencius). It determines what range of sensible discriminants counts as categories for moral purposes. Thus the categories mesh with the moral system of the sage - kings and match the clustering they originated.

It is clear that Xunzi absorbed a good deal of his contemporary theory of language. It is less clear if he understood the arguments and motivation. He deals with the problem of compound terms by ignoring it: 'If a single term is sufficient to convey the intent then use that and otherwise use a compound term.' The intent, presumably, is the conventionally understood intent. Xunzi does accept the Mohist view of names with varying scopes, and disowns the one-name-one-thing ideal. The only important kind of clarity or consistency is the constancy of convention.

Xunzi treats a number of related problems about names in sensitive fashion. He saw that spatial separation was a basis of describing two things of the same kind as two 'stuffs'. He then defines 'change' as being when a thing's spatial position does not change (exhibits characteristic continuity) and its type does. We then treat the thing as the same thing that has changed characteristics. This discussion of metamorphosis is the closest approximation of the classical Western problem of change (see Change).

Whether or not Xunzi understood the theories behind the paradoxes he criticizes, he clearly did not appreciate them. He exhibits no philosophical fascination with solving conceptual puzzles for their own sake or using them to drive theory. He criticizes paradoxical statements on primarily political grounds, namely the deleterious social effects of asserting their conclusions. Each upsets conventional ways of using terms. Xunzi's solution is political rather intellectual: ban them.

Xunzi classifies the paradoxes into three groups, which vaguely suggests the line of thought leading to them. Each, he argues, violates one of the three insights into names. The reason for naming is coordinating behaviour, so paradoxes which 'use names to confuse names' include the Mohist's claim that 'killing thieves is not killing men'. This uses a theory of names to yield a conclusion that sounds unconventional. So, we forbid saying them.

The second set 'use reality to confuse names', and the central examples are like Hui Shi's relativity paradoxes. These ignore the shared human empirical basis for assigning similarity and difference and use the fact that having different perspectives on reality might lead us to saying unconventional things about size and shape. So, the king will forbid saying them.

The final group use names to confuse reality and includes 'white horse not horse'. Xunzi's analysis does not help resolve the interpretive puzzles about the line of reasoning since it addresses only the pragmatic consequences of allowing such theorizing. His solution, once again, is for the king to avoid and prevent such distracting sophistry.

11 The aftermath: death of philosophy

One of Xunzi’s students, Han Feizi, was a minor royal in one of the Warring States, who became a central figure of the Legalist school. He had learned a smattering of Chinese theory of language, and he exaggerated the threat of interpretative anarchy to justify repressing philosophy and language creativity. He followed Xunzi’s argument that the ruler should enforce uniformity in language but rejected using a scholarly tradition as the norm. His theory of regulation and punishment was based on a crude argument about shape and name which takes us back to the unexplained Confucian notion that names by themselves guide action. An official post is a capsule description of functions (duties) the holder should perform. In the light of recent discoveries, this doctrine appears to be an application of the doctrine of a cult of ruler worship (Huang-Lao) which taught that the ‘guide’ was in nature and names were embedded in natural shapes.

Legalism became the official doctrine of the repressive Qin empire, which brought the classical period of Chinese philosophy to an abrupt halt (see Legalist philosophy, Chinese). In the aftermath, the insights of Chinese theory of language slipped into obscurity. Huang-Lao became the dominant theory surviving during China’s philosophical dark age until the importation of Buddhist theory. The early medieval Daoist interpreters argued that we can have names only for things we see. Suppression had worked its magic.

Logic in Islamic philosophy

Islamic logic was inspired primarily by Aristotle's logical corpus, the Organon (which according to a late Greek taxonomy also included the Rhetoric and Poetics). Islamic authors were also familiar with some elements in Stoic logic and linguistic theory, and their logical sources included not only Aristotle's own works but also the works of the late Greek Aristotelian commentators, the Isagōgēof Porphyry and the logical writings of Galen. However, most of the logical work of the Islamic philosophers remained squarely within the tradition of Aristotelian logic, and most of their writings in this area were in the form of commentaries on Aristotle.

For the Islamic philosophers, logic included not only the study of formal patterns of inference and their validity but also elements of the philosophy of language and even of epistemology and metaphysics. Because of territorial disputes with the Arabic grammarians, Islamic philosophers were very interested in working out the relationship between logic and language, and they devoted much discussion to the question of the subject matter and aims of logic in relation to reasoning and speech. In the area of formal logical analysis, they elaborated upon the theory of terms, propositions and syllogisms as formulated in Aristotle's Categories, De interpretatione and Prior Analytics. In the spirit of Aristotle, they considered the syllogism to be the form to which all rational argumentation could be reduced, and they regarded syllogistic theory as the focal point of logic. Even poetics was considered as a syllogistic art in some fashion by most of the major Islamic Aristotelians.

Since logic was viewed as an organon *or instrument by which to acquire knowledge, logic in the Islamic world also incorporated a general theory of argumentation focused upon epistemological aims. This element of Islamic logic centred upon the theory of demonstration found in Aristotle's Posterior Analytics, since demonstration was considered the ultimate goal sought by logic. Other elements of the theory of argumentation, such as dialectics and rhetoric, were viewed as secondary to demonstration, since it was held that these argument forms produced cognitive states inferior in certitude and stability to demonstration. The philosopher's aim was ultimately to demonstrate necessary and certain truth; the use of dialectical and rhetorical arguments was accounted for as preparatory to demonstration, as defensive of its conclusions, or as aimed at communicating its results to a broader audience.*

1 The subject matter and aims of logic

As was their custom in discussing all the branches of philosophy, the Islamic philosophers devoted considerable attention to identifying the subject matter studied by logic and the aims at which logical studies are directed. Al-Farabi, whose logical and linguistic writings comprise the majority of his philosophical output, epitomizes the approach to logic that is characteristic of Islamic Aristotelianism. In his *Ihsa' al-'ulum (Enumeration of the Sciences)*, he defines logic as an instrumental, rule-based science aimed at directing the intellect towards the truth and safeguarding it from error in its acts of reasoning. He defends the need for such a science of reasoning on the grounds that it is possible for the mind to err in at least some of its acts, for example, in those in which the intelligibles sought are not innate, but are rather attained discursively and empirically 'through reflection and contemplation'. Al-Farabi compares logic to tools such as rulers and compasses, which are used to ensure exactness when we measure physical objects subject to the errors of sensation. Like these tools, logical measures can be employed by their users to verify both their own acts of reasoning and the arguments of others. Indeed, logic is especially useful and important to guide the intellect when it is faced with the need to adjudicate between opposed and conflicting opinions and authorities.

Al-Farabi's view of logic as a rule-based science which governs the mind's operations over intelligibles is repeated in many of his introductory logical works, and it formed the foundation for Ibn Sina's later refinements (see Ibn Sina). In the opening chapters of his *al-Madkhal (Introduction)*, the first logical book of his encyclopaedic work *al-Shifa' (Healing)*, Ibn Sina describes the purpose of logic as one of enabling the intellect to acquire 'knowledge of the unknown from the known'. Like al-Farabi, he defends the need for logic by arguing that the innate capacities of reasoning are insufficient to ensure the attainment of this purpose, and thus they require the aid of an art. While there may be some cases in which innate intelligence is sufficient to ensure the attainment of true knowledge, such cases are haphazard at best; he compares them to someone who manages to hit a target on occasion without being a true marksman. The most important and influential innovation that Ibn Sina introduces

into the characterization of logic is his identification of its subject matter as 'second intentions' or 'secondary concepts', in contrast to 'first intentions'. This distinction is closely linked in Ibn Sina's philosophy to his important metaphysical claim that essence or quiddity can be distinguished from existence, and that existence in turn can be considered in either of its two modes: existence in concrete, singular things in the external world; or conceptual existence in one of the soul's sensible or intellectual faculties (see Existence).

In *al-Madkhal*, Ibn Sina argues that logic differs from the other sciences because it considers not conceptual existence as such (this would be psychology), but rather the accidents or properties that belong to any quiddity by virtue of its being conceptualized by the mind. These properties, according to Ibn Sina, include such things as essential and accidental predication, being a subject or being a predicate, and being a premise or a syllogism (see Logical form §1). It is these properties that allow the mind to connect concepts together in order to acquire knowledge of the unknown; they provide the foundation for the rules of reasoning and inference that logic studies. They are moreover formal properties in the sense that, as properties belonging to all concepts in virtue of their mental mode of existence, they are entirely independent of the content of the thought itself; they are indifferent to the intrinsic natures of the quiddities which they serve to link together.

In the *Ilahiyyat (Metaphysics)* of *al-Shifa'*, Ibn Sina introduces the terminology of first and second 'intentions' or concepts in order to express the relation between the concepts of these quiddities themselves - which are studied in the theoretical sciences - and the concepts of the states and accidents of their mental existence which logic studies: 'As you know, the subject matter of logical science is second, intelligible intentions (*al-ma'ani al-ma'qula al-thaniyya*) which are dependent upon the primary intelligible intentions with respect to some property by which they lead from the known to the unknown' (*Ilahiyyat* Book 1, ch. 2, in Anawati and Zayed 1960: 10-11). For example, the second intentions of 'being a subject' and 'being a predicate' are studied in logic independently of whatever first intentions function as the subject and predicate terms in a given proposition, for example, 'human being' and 'rational animal' in the proposition 'a human being is a rational animal'. The logical second intentions depend upon the first intentions because the first intentions are the conceptual building blocks of the new knowledge which second intentions link together: but logic studies the second intentions in abstraction from whatever particular first intentions the logical relations depend upon in any given case.

2 Logic, language and grammar

The attention that Ibn Sina and al-Farabi devote to the proper characterization of the subject matter of logic stems in part from a concern to distinguish logic from grammar. In the ancient and medieval traditions, the study of logic was closely tied to the philosophical consideration of language (see Language, medieval theories of; Logic, ancient; Logic, medieval), and for this reason many Arabic grammarians - whose linguistic theories were developed to a high degree of complexity and sophistication - were contemptuous of the philosophers for importing Greek logic, which they saw as a foreign linguistic tradition, into the Arabic milieu. This attitude toward Greek logic is epitomized in a famous debate reported to have taken place in Baghdad in 932 between the grammarian Abu Sa'id al-Sirafi and Abu Bishr Matta, a Syriac Christian who translated some of Aristotle's works into Arabic and is purported to have been one of al-Farabi's teachers. The extant account of the debate is heavily biased towards al-Sirafi, who attacks logical formalism and denies the ability of logic to act as a measure of reasoning over and above the innate capacities of the intellect itself. His principal claims are that philosophical logic is nothing but Greek grammar warmed over, that it is inextricably tied to the idiom of the Greek language and that it has nothing to offer speakers of another language such as Arabic.

It is against the background of such attacks that the discussions of the relations between logic, language and grammar by al-Farabi, Ibn Sina and al-Farabi's pupil Yahya ibn 'Adi (also a Syriac Christian and translator), are to be understood. Al-Farabi and Yahya both present essentially the same perspective on the relations between logic and language, a moderate perspective which Ibn Sina later rejects. In the *Ihsa' al-'ulum*, al-Farabi argues that logic and grammar both have some legitimate interest in language, but whereas grammatical rules primarily govern the use of language, logical rules primarily govern the use of intelligibles:

> And this art [of logic] is analogous to the art of grammar, in that the relation of the art of logic to the intellect and the intelligibles is like the relation of the art of grammar to language and expressions. That is, to every rule for expressions which the science of grammar provides us, there is a corresponding [rule] for intelligibles which the science of logic provides us.

(*Ihsa' al-'ulum*, in Amin 1968: 68)

More precisely, al-Farabi explains that although grammar and logic share a mutual concern with expressions, grammar provides rules that govern the correct use of expressions in a given language, but logic provides rules that govern the use of any language whatsoever in so far as it signifies intelligibles. Thus, logic will have some of the characteristics of a universal grammar, attending to the common features of all languages that reflect their underlying intelligible content. Some linguistic features will be studied in both logic and grammar, but logic will study them as they are common, and grammar in so far as they are idiomatic. On the basis of this comparison with grammar, then, al-Farabi is able to complete his characterization of the subject matter of logic as follows: 'The subject-matters of logic are the things for which [logic] provides the rules, namely, intelligibles in so far as they are signified by expressions, and expressions in so far as they signify intelligibles' (*Ihsa' al-'ulum*, in Amin 1968: 74).

Like al-Farabi, Yahya ibn 'Adi, in a treatise entitled *Maqala fi tabyin al-fasl bayna sina'atay al-mantiq al-falsafi wa-al-nahw al-'arab (On the Difference Between Philosophical Logic and Arabic Grammar)*, makes his case for the independence of logic from grammar based upon the differences between the grammar of a particular nation and the universal science of logic. He argues that the subject matter of grammar is mere expressions (*al-alfaz*), which it studies from the limited perspective of their correct articulation and vocalization according to Arabic conventions. The grammarian is especially concerned with language as an oral phenomenon; the logician alone is properly concerned with 'expressions in so far as they signify meanings' (*al-alfaz al-dalla 'ala al-ma'ani*) (*Maqala fi tabyin*, in Endress 1978: 188). To support this claim, Yahya points out that changing grammatical inflections do not affect the basic signification of a word: if in one sentence a word occurs in the nominative case, with the appropriate vocalization, its signification remains unchanged when it is used in another sentence in the accusative case and with a different vocal ending.

In Ibn Sina's view, however, such accounts of the logician's interest in language and its differences from that of the grammarian did not go far enough. In keeping with his own understanding of logic as the science which studies second intentions, Ibn Sina criticized such earlier attempts to introduce linguistic concerns into the subject matter of logic. In *al-Madkhal*, Ibn Sina labels as 'stupid' those who say that 'the subject matter of logic is speculation concerning expressions in so far as they signify meanings (*ma'ani*)'. However, Ibn Sina does not deny that the logician is sometimes or even often required to consider linguistic matters; his objection is to the inclusion of language as an essential constituent of the subject matter of logic. The logician is only incidentally concerned with language because of the constraints of human thought and the practical exigencies of learning and communication. Ibn Sina goes so far as to claim that, 'if logic could be learned through pure thought so that meanings alone could be attended to in it, then it would dispense entirely with expressions'; but since this is not in fact possible, 'the art of logic is compelled to have some of its parts come to consider the states of expressions' (*al-Madhkal*, in Anawati *et al.* 1952: 22-3). For Ibn Sina, then, logic is a purely rational art whose purpose is entirely captured by its goal of leading the mind from the known to the unknown; only accidentally and secondarily can it be considered a linguistic art.

3 Conceptualization and assent

While the close links between logic and linguistic studies emerge in the Islamic philosophers' consideration of the subject matter of logic, the links between logic and epistemology come to the fore in the consideration of the divisions within logic and the order of the books within Aristotle's Organon. All the principal Islamic Aristotelians organize their understanding of the divisions of logic around the epistemological couplet of *tasawwur* (conceptualization), and *tasdiq* (assent), which constitute for them the two states of knowledge that logic aims to produce in the intellect.

Conceptualization is the act of the mind by which it grasps singular (though not necessarily simple) essences or quiddities, such as the concept of 'human being'. Assent, by contrast, is the act of the intellect whereby it makes a determinate judgment to which a truth-value can be assigned; in fact, conceptualization is defined in Islamic philosophy principally by contrast with assent. Thus, any act of knowledge that does not entail the assignment of a truth-value to the proposition that corresponds to it will be an act of conceptualization alone, not assent. More specifically, the Islamic philosophers link assent to the affirmation or denial of the existence of the thing

conceived, or to the judgment that it exists in a certain state, with certain properties. Thus, assent presupposes some prior act of conceptualization, although conceptualization does not presuppose assent.

One of the purposes of including a consideration of the *tasawwur-tasdiq* dichotomy in introductory discussions of the purpose of logic is to provide an epistemological foundation for the two focal points of Aristotelian logic, the definition and the syllogism (see Logical form §1). The purpose of the definition is identified as the production of an act of conceptualization, and the purpose of the syllogism is identified as causing assent to the truth of a proposition. However, since the definition and the syllogism are both considered in the *Prior* and *Posterior Analytics* and the works that come after them in the Organon, the study of the ways of producing conceptualization and assent presupposes as its foundation the study of single terms and propositions in the *Categories* and *De interpretatione*.

4 Predicables, categories and propositions

In keeping with the ancient Greek tradition, the Islamic philosophers considered the books of the Organon to be an ordered series which begins with the study of the signification of simple terms in the *Categories* and then proceeds to the study of propositions in the *De interpretatione*. In addition to these two Aristotelian texts, a work of the Neoplatonist Porphyry, known as the *Isagōgē(Introduction)*, was appended to the beginning of this series as an introduction to the study of the *Categories* (see Aristotle §7). It was concerned with the five predicables: genus, species, difference, property and accident. While all of the Islamic Aristotelians wrote commentaries on the *Isagōgē* and utilized its grouping of the predicables, not all were convinced of its utility as an introduction to Aristotle. Ibn Rushd openly expresses such doubts in the introduction to his *Talkhis kitab al-maqulat (Middle Commentary on the Categories)*, where he indicates that his original intention was to omit the *Isagōgē* entirely from his series of middle commentaries on the Organon. At the end of his work on the *Isagōgē* itself, he explains bluntly that he does not believe that Porphyry's text is a helpful introduction to the study of logic and questions whether it is really a logical text at all. His sole reason for completing the commentary, he tells us, was to comply with a request made by his friends.

The logical character of the *Categories* presented a related problem for other Islamic philosophers. In the introduction to his *Sharh al-'ibarah (Great Commentary on the De interpretatione)*, al-Farabi rehearses some of the controversies inherited from the Greek tradition over the relations between the *Categories* and the *De interpretatione*. As al-Farabi points out, the *De interpretatione* can be understood quite well without a prior knowledge of the *Categories*, and the former work makes no explicit references to the latter. Moreover, the *De interpretatione* is principally concerned with the formal relations amongst propositions, such as contradiction and contrariety, whereas the *Categories* is concerned with the signification or meaning of terms as such. Furthermore, in its opening chapters, the *De interpretatione* considers in formal terms the simple parts of which propositions are composed, that is, the noun and the verb. Despite these concerns, however, al-Farabi opts for the traditional ordering of these books on the grounds that the *Categories* is relevant to the whole of logic, since it studies 'the simplest of the subject matters in which logic actualizes itself'. In his *Falsafa Aristutalis (Philosophy of Aristotle)*, al-Farabi opts for a similar solution to the logical status of the Categories, explaining that it comprises an investigation and classification of 'the instances of being from which the first premises are compounded', which are 'the primary significations of the expressions generally accepted by all' (*Falsafa Aristutalis*, in Mahdi 1969: 82-3).

Al-Farabi's misgivings in both of these texts stem from the largely ontological focus of the Aristotelian *Categories*, which calls into question its placement within the Organon. This concern was echoed later by Ibn Sina, who points out that many of the discussions in the *Categories* would be better placed in metaphysics or psychology, since they pertain to the study of expressions as directly signifying external or mental beings, in other words, to first rather than to second intentions. But since the *Categories* is useful in instructing us how to formulate definitions - which is one of the principal goals of logic - its placement in the Organon can be justified on practical grounds.

Islamic philosophers viewed *De interpretatione* as a study of the composition and truth-values of categorical propositions. Thus al-Farabi, in his great commentary on this text, explains that the term 'interpretation' used in the title of the work means 'complete statement' (*al-qawl al-tamm*). A complete statement, according to al-Farabi, must be one which causes a complete understanding in the mind; in other words, one in which assent occurs along

with conceptualization. This is achieved principally by a simple, predicative, categorical statement (*al-qawl al-jazim al-hamli al-basit*) which affirms or denies a predicate of its subject.

5 Theory of argumentation

For the entire Islamic tradition, the crowning glory of Aristotelian logic is the syllogistic theory outlined in the *Prior* and *Posterior Analytics*, especially the latter. The purpose of logic is to provide the means whereby knowledge is to be acquired, and the most valuable type of knowledge is that which is certain and necessary, that is, knowledge gained according to the paradigm of demonstrative science laid out in the *Posterior Analytics*. This part of logic, in the words of al-Farabi's *Ihsa' al-'ulum*, is 'the strongest and pre-eminent in dignity and authority. Logic seeks its primary aim in this part alone, and the rest of its parts are only for its sake' (*Ihsa' al-'ulum*, in Amin 1968: 89). Even the formal study of the syllogism itself is primarily undertaken for the sake of its employment in demonstrations.

In their formal syllogistic theory, the Islamic Aristotelians mainly follow Aristotle's *Prior Analytics*. While they are aware of the fourth figure traditionally ascribed to Galen, the tendency is to dismiss this figure as superfluous and intuitively implausible, as Ibn Sina does in the seventh method of his *al-Isharat wa-'l-tanbihat (Remarks and Admonitions)*; or to ignore it entirely, as al-Farabi does in his *Kitab al-qiyas (Book on the Syllogism)*. Similarly, the Arabic philosophers knew of the alternative propositional logic of the Stoics and incorporated elements of it in their discussions of conditional or hypothetical (*shartiyyah*) syllogisms (see Logic, ancient). However, they did not accept the Stoic inference schemata, nor did they treat conditional connectives as truth-functional, since they did not consider the parts of conditional statements to be complete propositions in their own right. Moreover, for the Islamic logicians 'conditional' was a generic term which included both 'conjunctive' (*al-muttasilat*) conditionals (of the form, 'if… then') and 'disjunctive' (*al-munfasilat*) conditionals (of the form, 'either… or'). Conditional syllogisms of both sorts were viewed as relying upon a process of 'reiteration' or 'repetition' (*istithna'*), a term which referred to the repetition of the antecedent or the consequent, or one of the two disjuncts, in so far as it formed the second premise of a syllogism. Thus in the conjunctive conditional syllogism, 'If it is daytime, then it is light; but it is daytime, therefore it is light', 'it is daytime' would be labelled the *mustathna'* or reiterated premise, since it is by its restatement that the syllogism reaches its conclusion.

When we turn to the specific application of syllogistic theory to particular types of argumentation, the epistemological concerns of Islamic logic surface once more. In particular, the Islamic philosophers explained the primacy of demonstration, and the ancillary role of dialectical, rhetorical, poetic and sophistical syllogisms, by reference to the epistemic status of the premises used in each type of syllogism, and the type of assent they could produce to the conclusion of the syllogisms in which they were employed. The classification of syllogisms and their premises according to the nature of their assent is found in the logical writings of all the major Islamic philosophers, but the most complete and systematic classification of premises occurs in three of Ibn Sina's works, *al-Burhan (Demonstration)*, in *al-Shifa'*, *al-Najah (Deliverance)* and *al-Isharat wa-'l-tanbihat (Remarks and Admonitions)*. Although these three accounts differ somewhat in the number and variety of the premises listed in each, generally they present a single and consistent theory. Demonstrative syllogisms are composed of premises which necessitate assent and include self-evident first principles as well as sensible, empirically evident propositions. Dialectical syllogisms are based upon generally accepted beliefs (*al-mashhurat*), which are equivalent to the *endoxa* of Aristotle's Topics; on premises granted for the purposes of dialectical debate; and in general, on all premises assented to because they are universally accepted by all people, or by people deemed authoritative. Rhetorical syllogisms are similar to dialectical ones, except that they are accepted unreflectively and on the basis of a more limited authority, relative, for example, to a particular group or sect; as such, they are only supposed or presumed to be 'generally-accepted beliefs'. Sophistical premises are those accepted because of some misleading resemblance to another type of premise, and poetic premises are those that produce a motion in the faculty of imagination (*al-takhyil*), not an act of intellectual assent.

The inclusion of rhetorical and poetical syllogisms in this enumeration reflects a common assumption among Islamic philosophers that Aristotle's *Rhetoric* and *Poetics* are parts of his logical Organon. This assumption was inherited by the Islamic tradition from the Greek commentators, and it was used by them in part to account for the differences between philosophical and popular modes of discourse and argumentation, particularly in the context of discussions of the relations between philosophy and religion. The Islamic philosophers held that whereas

philosophers rely principally upon demonstrative and dialectical syllogisms, religious leaders and theologians generally use rhetorical and poetical syllogisms to persuade the general populace. Religion is thus viewed as an image or reflection of philosophical, demonstrative truth propounded in language and argument-forms that can be easily understood by the mass of humanity.

The place of dialectic within the theory of argumentation is perhaps the most ambivalent in Islamic logic. While dialectic is seen as inferior to demonstration, its importance for philosophy is none the less recognized. A good example of this is found in al-Farabi's enumeration in his *Kitab al-jadal (Book on Dialectic)* of the ways in which dialectic serves philosophers. According to al-Farabi, dialectic hones argumentative skills, introduces the principles of the special demonstrative sciences, alerts the mind to the self-evident principles of demonstration, helps to develop communicative skills and provides the means for refuting sophistry. Of these five uses, only the fourth is external to the proper aims of philosophy and closer to the tasks usually reserved to theology and religion. The other four pertain to the learning or acquisition of truly philosophical skills, even if they lie outside the strictly demonstrative aims that are the ultimate end of philosophy.

In the case of the theory of demonstration itself, Islamic logicians organized their commentaries on the *Posterior Analytics* around the definition and the demonstrative syllogism as the means by which both conceptualization and assent are most perfectly attained. Al-Farabi's *Kitab al-burhan (Book on Demonstration)* offers an excellent summary of the standard approach taken by Islamic philosophers to theory of demonstration and its epistemological aims. Just as he identified the categorical statement as the embodiment of perfect assent on the propositional level, here al-Farabi identifies demonstrative certitude as complete or perfect assent on the level of syllogistic inference. Moreover, certitude is defined by al-Farabi in terms of what we would now label 'second-order' knowledge:

> Certitude is for us to believe, concerning the truth to which we have assented, that it is not possible at all for what we believe about this matter to be different from what we believe it to be; and in addition to this for us to believe, concerning our belief, that another belief is not possible - in the sense that whenever some belief about the first belief is formed, it is impossible for it to be otherwise, and so on *ad infinitum*.
>
> (*Kitab al-burhan*, in al-'Ajam and Fakhry 1986-7, 4: 20)

Certitude requires not just knowledge of a conclusion, *p*, but knowing that we know *p*. This sort of certitude al-Farabi calls 'necessary certitude'. However, he also allows for non-necessary certitude, which holds 'only at a particular time', and thus can be applied to propositions about merely contingent beings: 'Necessary certitude and necessary existence are convertible in entailment, for what is verified as necessarily certain is necessarily existent' (*Kitab al-burhan*, in al-'Ajam and Fakhry 1986-7, 4: 22). While al-Farabi recognizes both of these varieties of certitude to be forms of perfect assent, in his view necessary certitude alone fulfils the strict conditions of Aristotelian demonstration, since it alone will pertain to objects which cannot be other than they are.

Al-Farabi's remarks on the utility of dialectic, combined with his extension of the notion of perfect assent beyond the confines of strict and necessary demonstration, illustrate the overall breadth of the Islamic philosophers' theories of argumentation. Despite their professions of the primacy of the demonstrative paradigm within philosophy, the Islamic Aristotelians recognized a broad range of legitimate and useful argument forms and acknowledged their importance as philosophical tools leading to knowledge of the unknown.

Logic in Japan

'Logic' became an explicit topic in Japanese philosophy only in the twentieth century. Most effort has been directed to developing a dialectical logic in a Hegelian mode rather than a symbolic system. The Japanese term coined for logic in this sense is ronri *(the 'principles of discourse or argument'). The term* ronrigaku *(*ronri *+ -ology) is the more common term for formal, symbolic logic. In the twentieth century two Japanese philosophers, Nishida Kitarō(1870-1945) and Tanabe Hajime (1885-1962), developed distinctive dialectical logics that drew on key assumptions from traditional Japanese thought, but followed a Western style of analysis and articulation.*

Nishida's logic of basho *(place,* topos, *field) located the contextual premises of empirical and idealist judgments within a trans-judgmental domain called the 'acting-intuiting'. He related this to his logic of the predicate, which rejected the Aristotelian priority of the grammatical subject as signifier of substance, instead making the subject the qualifier of the predicate, the signifier of the event. Tanabe criticized Nishida's system as ahistorical and transcultural. His logic of species gave priority to the specificity of cultural and historical embededness, the middle ground between the universal ought and individual freedom.*

1 Dialectical logic

To appreciate the development of logic in modern Japan, it is useful to bear in mind three tendencies from traditional Japanese philosophy. First, Japanese thought has tended to emphasize internal rather than external relations. That is, in a relationship the two relatents, *a* and *b*, are generally understood to be not separate entities that have been connected by a relating principle, but to be two overlapping entities: part of *a* is *b* and part of *b* is *a*. Traditional Buddhist philosophy assumes no entity ever exists independently as a discrete substance; it is always in flux and depends for its existence on some other entity (see Buddhist philosophy, Japanese).

The second point in traditional Japanese thought is the application of internal relations to the part/whole model (see Mereology). In esoteric, Tendai and Kegon Buddhism, the whole has typically not been understood as simply the sum of the parts. Because the whole and parts are internally related, the part (as in a recursive set) always reflects in some way the whole.

The third point about traditional Japanese thought is that even opposites are often understood as being internally related. If, therefore, *a* and not-*a* overlap in some way, that suggests that *a* can only be fully *a* insofar as it contains something of not-*a*. At the least, in defining an entity, it is typically distinguished from and therefore related to its opposite. In East Asian texts, such as the translation of the Indian Buddhist *Perfection of Wisdom* texts, the Sino-Japanese term *soku* is commonly used to express this identity within difference: *a soku* not-*a*. The term *soku* can be used as a special kind of copula or can be used as a phrase meaning something like 'that is to say'. English translations (not completely successfully) tend to capture this sense by using the Latinate phrases '*a qua* not-*a*' or '*a sive* not-*a*' (see Kyoto School §3).

When Western philosophy entered Japan in the latter half of the nineteenth century, Japanese philosophers became aware that the dominant Western modes of logical expression could not adequately express the premodern tendencies just explained. Among Western systems, Hegel's dialectical logic (see Hegel, G.W.F.) seemed to most resemble the *soku* way of relating opposites and many Japanese philosophers studied it intensely in the early twentieth century. In the end, however, most Japanese philosophers found it unacceptable. In fact, it seemed almost the mirror image of the kind of dialectical logic sought by the Japanese. First, Hegelian logic is grounded in being, whereas traditional Asian (especially Buddhist and Daoist) philosophy gave more primacy to nonbeing or nothingness. Second, the Hegelian system of dialectic expresses how static beings are transformed into events of becoming. In Japanese thought, however, events are the starting point and logical analysis is used to abstract from it discrete beings within the becoming. Third, the Hegelian dialectic is progressive. It shows the development of thought through time into what it is becoming. In Japanese thought, however, the dialectical process is more commonly used regressively to understand how thought comes about and out of what it is formed. Therefore, although modern Japanese philosophers have continued to use the term 'dialectic' (*benshōhō*), except for Marxists and certain other neo-Hegelians, the term usually refers to a distinctively Japanese logic of dialectic.

Two of the best known dialectical Japanese logics were developed by Nishida Kitarō (1870-1945) and Tanabe

Hajime (1885-1962). Both figures were trained in mathematics (in fact, in his younger days, Tanabe was Japan's most renowned philosopher of mathematics and science), well versed in Hegelianism and steeped in Buddhism (Nishida was a Zen Buddhist, Tanabe a Pure Land Buddhist). Both belonged to what is often called the Kyoto School of Japanese philosophy.

2 Nishida's logic of *basho* and logic of the predicate

Nishida attacked Western paradigms of logic from two directions, epistemological and metaphysical/syntactical. When taking the former approach he generally spoke of his logic as the 'logic of *basho*'. *Basho* is an ordinary Japanese word meaning 'place' that can serve as an equivalent for the technical terms *topos* or 'field'. Nishida understood the philosophical construction of reality to take place within three experiential domains or *basho*: empiricism, idealism and what he called the 'acting-intuiting'. The empiricist speaks from out of the '*basho* of being'; that is, the empiricist judges the world of physical entities (see Empiricism). The idealist, on the other hand, judges the world of psychological entities, showing their role in the construction of our experience of physical entities (see Idealism). This is the realm of consciousness, experience, self and the transcendent ego. Sometimes the Kyoto School refers to this as the '*basho* of relative nothingness', because from the standpoint of the empiricist this psychological world is considered so transparent as to be omitted from the discussion of what is. Relative to empirical reality, it is a place of nothingness.

The third *basho* is supposedly less commonly articulated in the West, although Nishida found suggestive references to it in William James, Bergson, some neo-Kantians and some religiously or aesthetically oriented philosophers. The third *basho* is where knowing and doing are virtually a single act. It occurs when a person responds spontaneously without deliberation to the information being intuited, or when their intake of information is the same act as going out and gathering information. Nishida calls that immediacy the single event of 'acting-intuiting'. This realm is unknown to the categories of both the empiricist's material world and the idealist's inner world. In fact, in its immediacy and oneness, it cannot be analysed in any systematic way at all. Therefore, it can be called the '*basho* of absolute nothingness' (see Buddhist concept of emptiness).

In themselves, these three realms may constitute the contents of kinds of knowing, but Nishida argues there is a formal connection among them: there is a hierarchical 'logic of *basho*'. His analysis of the hierarchy is based in his evaluation of how the *basho* are implicated in each other through the logical analysis of the conditions of judgment. Consider an empirical judgment such as 'The cat is black'. Nishida asks in what place, in what *basho*, one is standing when making that judgment. He argues that for such an empirical judgment to be made, one must have an experience of perceiving that black cat. In other words, one assumes there is a perceiver and a perception that makes the judgment possible. Once we recognize this fact, we realize that judgments within the *basho* of being are logically dependent on experience within the *basho* of relative being, the idealist's world of consciousness and perception. In turn, I may ask about the judgment of 'I see that the cat is black'. That judgment of the *basho* of relative nothingness is itself only possible as a reflection and abstraction out of an experience of the acting-intuiting. So, the *basho* of relative nothingness has as its logical precondition experience within the *basho* of absolute nothingness. The acting-intuiting, being immediate and unitary, is not itself capable of making judgments; yet at the same time, it is the totality out of which reflection can generate the judgments of either idealism or empiricism. For Nishida, it is the universal that becomes concrete through the mediation of the other two *basho*. In this way Nishida's dialectic takes us from the simplest of truths, the empirical judgment, to show regressively its logical basis in the immediacy of absolute nothingness.

Nishida also attacked the Western bias of the ontology of being over nonbeing, of substance over event and of the grammatical subject over the grammatical predicate (see Being; Substance; Events; Syntax). Instead of the Aristotelian model in which the sentential subject is correlated with the metaphysical substance and the predicate with the attribute, Nishida proposed a 'logic of the predicate'. In his logic, the primary unit of reality is the event, and only through abstraction do we separate out of that event the sentential subject or the ontological substance. The predicate is a universal whose function becomes concrete and specified through the sentential subject. In doing so, Nishida has in effect made the substance into an attribute of the event. By changing the metaphysical priority from substance to event and the logical or syntactic priority from subject to predicate, Nishida's Buddhism-inspired logic is grounded in change or process rather than stasis or essence. When merged with the threefold model of the logic of *basho*, Nishida attempted to develop a comprehensive philosophical system

including a metaphysics, a phenomenology, an epistemology and an analysis of judgment. His system was at once intelligible to Western analysis, yet simultaneously continuous with the premodern Japanese intellectual tradition.

3 Tanabe's logic of species

Tanabe criticized Nishida's logic of *basho*, proposing two qualifications or fundamental modifications. First, he questioned the implicit assumption that a totally unmediated experience (the acting-intuiting) is possible. Second, he believed Nishida's system was too simplistic in postulating a direct relation between the individual and the universal without the mediation of culture or society. He believed that without taking account of ethnicity and nationality, we cannot truly understand the dialectical development of thought and value through history. The arena of human activity is the social realm, not the unmediated realm of the acting-intuiting, nor the abstracted realm of intellectual philosophical positions like idealism and empiricism.

Tanabe referred to the level of the transcendent universal (that is, not conceptually particularized) totality as the level of 'genus'. Below it is the level of 'species', and below that the level of the 'individual'. In social terms, the logic of genus applies to humankind as a whole, the source of absolute values for ethics and the spiritual basis for the state. The logic of the individual, on the other hand, applies to epistemological judgment and the basis of personal creativity. Between the two lies the logic of species that applies to particularized ethnic, cultural and national values. Without that mediated middle realm, the actual lived experience of human action cannot be explained.

Tanabe began to develop his logic of species during the 1930s, but as he observed developments in Japan during the militarist period, he began to build into the system a more explicit mechanism of self-criticism. He did not feel free to publish his revisions until after the Second World War, however, at which point he emphasized the self-critical moment in his system by developing the philosophical concept of *range*. He himself translated this term as 'metanoia', a philosophical and personal sense of repentance and conversion that leads one to question the absoluteness of any philosophical system one has devised. Essentially, the dynamic of the logic of species is to be the dialectical mediation between the totalitarianism of the genus and the liberalism of individual. From the genus, the species derives the sense of absolute transcendent values applicable to all mankind; from the individual, the species derives the pragmatic concerns of working toward the particular benefit of one's fellow individuals. The nation, indeed the collective or personal activity of any human endeavour, can therefore never speak with the authority of the absolute; on the other hand, no such endeavour can ever be truly individual either, because all expression is enmeshed in the social. Once again, the realm of human activity is not that of fixed being, but that of Buddhist mediation, interdependence and a dialectical tension that deconstructs any system as soon as it makes it claim to be either absolute or individualistic.

Logic in the 17th and 18th centuries

Logic in the seventeenth century was characterized by attempts to reconcile older viewpoints, such as those of Ramus and Melanchthon, and by criticism of the nature and scope of traditional logic. F. Bacon indicated induction, rather than deduction, as the object of logic, thus opening the way for a logic of the empirical sciences. Descartes proposed to replace the complicated precepts of old logic by simple rules of method. However, even the authors of the Port-Royal Logic, who were influenced by Descartes, could not follow him all the way and continued to teach traditional doctrines, albeit with a new attention to the doctrine of ideas. Other logicians, following Locke, tried to modernize logic by concentrating on an analysis of human cognitive faculties, of the idea-word relation and of other than certain knowledge, thus broadening the scope of logic so as to account for probability. Another suggestion for the improvement of logic came from those who thought that logic should assume mathematics as an example either for its axiomatic-deductive method or for the inventive techniques of algebra. The last of these suggestions prompted research in the area of logical calculi. But this kind of research benefited from the doctrines devised by non-mathematically oriented authors who thus provided the logical framework in which algebraic techniques would be tried. This general background accounts not only for the exceptional logic of Leibniz, but also for some logical calculi worked out in the eighteenth century.

1 Seventeenth-century eclecticism

Seventeenth-century logic was conditioned by the debate of the previous two centuries for and against Aristotelianism and scholasticism, both of which had a quasi-autonomous life until well into the eighteenth century, so that differences of opinion persisted.

However, followers of Aristotle's defender Philip Melanchthon and of the anti-Aristotelian Petrus Ramus merged to form a Philippo-Ramist or Semi-Ramist school (see Logic, Renaissance §5). They restored the parts of Aristotelian logic left out by Ramus (conversion, the square of opposition, categories, demonstration, fallacies), but also attended to Ramist doctrines (for example, definition and division). The Philippo-Ramist B. Keckermann published a*Systema Logicum* (1600) in which he assigned to logic the aim of being systematic, that is, of being a first science directing the human mind; hence the additional name of Systematics given to his followers, such as J.H. Alsted, author of *Clavis Artis Lullianae (A Key to Lull's Art)* (1609) and *Logicae Systema Harmonicum* (1614), and R. Sanderson, who wrote a *Logicae Artis Compendium* (1618).

Eclecticism also characterized followers of the sixteenth-century logician J. Zabarella, according to whom Aristotle had provided an analytic method of discovery ('*regressus*') for mathematical demonstrations. Many seventeenth-century Zabarellists endorsed Ramist and scholastic doctrines, including F. Burgersdijck, whose *Institutionum logicarum libri duo (Two Books of Logical Institutions, 1626)* became the standard handbook in the Netherlands.

Another eclectic, J. Jungius, was one of the outstanding logicians of the century. He was acquainted with Philippo-Ramist dialectic and with the then recent scholasticism of Fonseca and Suarez. He also had Systematic and Zabarellist teachers and admired the *logistica* of Viète. In his *Logica Hamburgensis* (1635) he dealt with a logic of relations, non-syllogistic inferences, contraposition and special syllogisms.

2 Criticism of the syllogism

However, some of the major philosophers of the seventeenth century persisted in criticizing traditional logic, in particular the syllogism. In his *Instauratio magna* (1620) Francis Bacon, while acknowledging the cogency of the syllogism, observed that it cannot guarantee that the ideas occurring in it are abstracted from reality and defined correctly. Since induction presides over the abstraction and definition of ideas, he indicated induction, rather than deduction, as the object of logical research, thus opening the way for a logic of the empirical sciences.

Descartes repeated the sceptical argument that the syllogism, apart from being sterile, begs the question and has no more claim to certainty than non-inferential truths. As is clear from his *Regulae* (1628), for him the problem of inference was not how to infer (since we do this naturally), but how to infer with certainty. Descartes' solution to this problem rests on an analysis of our scientific knowledge which singles out two cognitive operations: intuition and deduction. Intuition is the basic operation because it makes us certain of simple propositions, whereas

deduction is just a chain of successive intuitions. Having found this solution, Descartes saw little use for a complicated logic: indeed, he considered it detrimental to the natural light of reason. As a substitute he listed, in the *Discours de la méthode* (1637), some rules of method meant as mere guidelines for the cognitive operations whose certainty he claimed to have explained.

3 Logic after Descartes

So limited a scope for logic was by no means universally accepted. For example, H. Fabri [Mosnerius] in the first tome of his *Philosophia* (1646) joined late medieval doctrines to mathematics and devised a combinatory calculus of 576 syllogistic moods in all figures. He also introduced truth tables based on three truth-values: truth, falsity and partial falsity. Later in the century independent research was pursued at a higher level in the *Logica demonstrativa* (1697) of G. Saccheri. He emphasized the demonstrative role of the so-called '*consequentia mirabilis*' showing that 'If not *p* then *p*' entails '*p*'.

But even scholars who accepted Descartes' rules of method as the core of logic had to account for traditional doctrines. This is clear from the *Logica vetus et nova (Old and New Logic)* (1654) of Clauberg; and even more from the *Logica restituta* (1662) of the independent Cartesian A. Geulincx, who revived medieval doctrines, related disjunction, conjunction and negation by means of their truth-conditions and devised a 'logical cube' whose faces represented logical axioms and forms of argumentation.

Old and new doctrines were also adopted in *La Logique ou l'art de penser* (1662), known as 'The Port-Royal Logic', by A. Arnauld and P. Nicole. The authors referred to Descartes' views (the 1664 edition mentions the manuscript of Descartes' *Regulae* (1628), and showed appreciation of Pascal's theory of definition, probability and method (they included a special section on method, imitated by many subsequent logics), and of Augustine's theory of language, from which their attentiveness to the idea-word relation was derived. As for traditional instruction, their syllogistic was more accurate than might be expected of a Cartesian logic. For they devised a combinatory calculus of possible moods with rules to choose the valid ones, and correctly warned against confusing the fourth figure and the first figure with transposed premises. None the less, the Port-Royal logicians agreed with Descartes that deduction has a derivative importance as compared with judgment. And given that they defined judgment as a comparison of ideas, they paid great attention to the ideas themselves. The Port-Royal doctrine of ideas revolves around the notions of comprehension (later, 'intension') and extension. The comprehension of an idea consists of the attributes it comprises in itself that cannot be removed from it without destroying it; the extension of an idea consists of the subjects with which the idea agrees. Comprehension and extension stand in inverse relation: the greater the comprehension of an idea, the smaller its extension, and vice versa. This relation regulated all other relations between ideas and operations (for example, abstraction and composition) performable on them.

The influence of Port-Royal doctrines upon French logic was evident right up to the end of the eighteenth century, for example from the *Logique* (1780) and the *Langue des calculs (Language of Calculi, 1798)* of É.B. de Condillac. In England the Port-Royal Logic was acknowledged even by scholars of a declared Aristotelian disposition, such as J. Wallis, who, in his *Institutio logicae* (1687), rejected Ramist syllogisms with singular terms and classified syllogistic figures competently. H. Aldrich, too, though mostly concerned with his valuable presentation of syllogistic, mentioned Port-Royal doctrines when discussing methodology and the history of logic in his *Artis Logicae Compendium* (1691).

4 The emergence of a logic of cognitive faculties

Towards the end of the seventeenth century, logic began to centre increasingly on an analysis of cognitive faculties. Such an analysis, introduced by Descartes, was carried further in the *Essay concerning Human Understanding* (1690) of John Locke and was the stepping-stone to what has been called 'facultative logic'. In this kind of logic the content of ideas is as important as their form, and equally important are the signs designating ideas. This not only explains why Locke equated logic with semiotics, but also gives an insight into the origins of the importance of language for later philosophy and logic.

The logic of cognitive faculties was promoted by the success of Locke's philosophy which, especially in Germany (for example, in the 1752 *Vernunftlehre (Doctrine of Reason)* of G.F. Meier), was often preferred to Descartes'

because of its avoidance of innate ideas and its applicability to other than certain knowledge (which later brought the study of probability within its scope). The influence of Locke's philosophy is evident in England in both the *Logick* (1725) and the *Improvement of the Mind* (1741) of I. Watts, who proposed a mixture of Locke with Port-Royal, as well as in the *Elements of Logick* (1748) of W. Duncan and the *Logicae compendium* (1759) of F. Hutcheson. Locke also influenced the *Système de réflexions* (1712) of the Swiss J.P. de Crousaz.

5 Logic and mathematics

At almost the same time as the birth of the logic of cognitive faculties, another image of the discipline began to emerge. It was born of the conviction that logic compared unfavourably with mathematics.

Some ascribed the superiority of mathematics to its axiomatic-deductive method. Indeed, Descartes' rules of method were interpreted as recommendations to start with a few simple and acknowledged notions (axioms) and thence to proceed to unknown ones (theorems). The supporters of such an interpretation maintained that the axiomatic-deductive method should replace logic and be the model for the right conduct of understanding. A prime example of this view is the *Medicina mentis* (1687) of von Tschirnhaus, who indicated the mathematical method as a therapy in all fields of knowledge and practical life.

Some attributed the superiority of mathematics to the problem-solving and inventive techniques of algebra. The search for equations relating unknown elements with given elements, exemplified in Descartes' *Géométrie* (1637), was considered the true Cartesian logic and was absorbed into the tradition which viewed mathematics as a universal science of invention (*mathesis universalis*).

This assessment of the merits of algebra outlived the imitation of the mathematical method: the latter was either reduced to a mere synthetic order of exposition, or restricted to mathematics because its wider use was held responsible for the degeneration of Cartesianism into Spinozism. Algebraic tools, on the other hand, were fitted for use in the construction of logical calculi. Despite this, the calculi which were actually or tentatively constructed at the time are not comparable to the later algebra of logic, mainly because they were still bound to the quantitative interpretation of algebra.

6 Leibniz and the emergence of logical calculi

Leibniz's logical calculus is connected with his project of an '*ars characteristica combinatoria*', whose accomplishment required (1) an alphabet of thoughts and appropriate symbols for it, (2) a rational grammar common to all languages, (3) an encyclopedia of the sciences and (4) a universal science by which the contents of all sciences would be ordered systematically and combined so as to discover new truths. This last requirement, in its turn, demanded a logical calculus.

Leibniz could not achieve his entire project, but none the less he wrote several incomplete versions of a logical calculus in papers dating from 1679 to the early 1690s (see Leibniz 1966). Common to all versions - which were related to Leibniz's many logical interests (syllogistic, logic of relations, modality and so on), as well as to his monadology - is the idea that a '*calculus ratiocinator*' is a mechanical procedure for drawing conclusions. It is based on: a universal mathematics similar to algebra; symbols standing for concepts or for propositions; and substitution rules governed by the principle that what is concluded with certain variable letters can be concluded equally with other letters satisfying the same conditions.

For all its exceptionality and complexity Leibniz's calculus represents a development of logic that can also be found in others' work which came soon after. This did not depend on Leibniz's direct influence because his calculus remained unpublished until the nineteenth century. The likely explanation is the existence of certain favourable conditions: the reputation of algebra as a universal means of discovery (see §5); and the existence of doctrines of ideas such as that of Port-Royal and the emerging logic of cognitive faculties (see §§3, 4 above). In this respect Cartesian logic and the logic of cognitive faculties were only apparently disconnected from logical calculi: the former provided the latter with a logical field of application. Indeed Locke, who belittled syllogistic, hoped for an algebra of logic. Admittedly, he did not construct a logical calculus and nor did Hobbes, despite his statement in *De Corpore* (1655) that ratiocination is computation. But an early attempt made by Jakob Bernoulli to establish a *Parallelismus ratiocinii logici et algebraici* (1685), while ending in admitted failure, was demonstrably based on a comparison of algebra with the Port-Royal doctrine of ideas.

7 Logical calculi in the eighteenth century

Between the 1740s and the 1760s progress both in the study of ideas and in algebra prompted a number of logical calculi by German-speaking authors.

The theory of ideas had been much developed in Germany due to the influence of A. Rüdiger. In his *De sensu veri et falsi* (1709) he maintained that the syllogism can be a means of discovery provided that, given a premise, we connect one of its terms with a new concept that stands in one of a set of well-defined idea-relations with the other term. For example, by connecting the predicate-term of a universal affirmative premise with any concept subordinated to the subject-term, we establish enthymematically the conclusion of a 'synthetic syllogism'. In general, Rüdiger's point was that if the syllogism can be used to discover truths, then logic does not have to be given a mathematical formulation in order for it to be inventive.

Taking the contrary viewpoint, Christian Wolff supported a mathematical view of logic maintaining that all mathematical demonstrations consist of chains of syllogisms in the first figure. Therefore in his *Vernünfftige Gedanken von den Kräfften des menschlichen Verstandes (Rational Thoughts on the Powers of the Human Understanding)* (1713) and his *Philosophia rationalis* (1728) he considered it futile to advocate the mathematical method as a substitute for logic or to charge traditional logic with being sterile and nugatory.

In the 1730s a number of authors, strengthened by the confidence in the value of logic characterizing the then dominant Wolffism, resumed logical work even along lines unforeseen by Wolff. In particular, J.P. Reusch in his *Systema logicum* (1734) gave a description of judgments and inferences as based on a set of idea-relations (reminiscent of Rüdiger) and on a principle of substitutivity for ideas.

But Reusch did not take the further step of building a calculus of idea-relations. This step was taken by J.A. Segner in his *Specimen logicae universaliter demonstratae (An Example of a Universally Demonstrated Logic, 1740)*. By using the notion of containment in intension and by an accurate employment of negative terms, he classified, assigned symbols to, and subjected to a set of rules the five idea-relations later known as the Gergonne relations. This produced a rare and beautiful example of a calculus applicable to syllogistic and to some non-syllogistic inferences.

An extensional perspective was chosen by G. Ploucquet in his *Fundamenta philosophiae speculativae* (1759). In his syllogistic calculus all concepts, including predicates, are quantified and there is a single general rule stating that concepts must retain in the conclusion of an argument the quantity they have in the premises.

Many topics were treated by J.H. Lambert in his *Neues Organon* (1764), ranging from probabilistic inference to symbolic knowledge to a theory of truth and error. In it he also represented the A, E, I, O propositions and syllogisms extensionally by means of straight lines. Such diagrams were independent of but served the same purpose as the circles used by Euler in his *Lettres à une Princesse d'Allemagne sur divers sujets de physique et de philosophie (Letters to a German Princess on Various Subjects of Physics and Philosophy, 1760-2)*. Circles, lines and other figures had also been used by J.C. Sturm (*Universalia Euclidea*, 1661), J.C. Lange (*Nucleus logicae Weisianae*, 1712), Ploucquet and the then unpublished Leibniz. But Lambert's most interesting contribution to logic is a calculus he worked out in letters and in some of his *Logische und philosophische Abhandlungen (Logical and Philosophical Essays, 1782- 7)* which were published after his death. He based it on concepts, their mutual interrelationships, and on the similarities between logical and algebraic operations. This calculus - which allowed for a tentative logic of relations and was capable of expressing composite propositions - was intensional. This feature was criticized by the Ploucquetian G.J. Holland in a letter (1765) to Lambert in which he sketched his own, extensional calculus. (For a comparison of Lambert's and Ploucquet's calculi see Bök (1766).)

Interest in logical calculi faded in the later part of the eighteenth century due, in all likelihood, to the influence of Kant's ideas on logic. In his *Nova dilucidatio (New Exposition, 1755)* Kant had maintained that Leibniz's *combinatoria* was far from being a genuine '*ars inveniendi*' but apparently did not deny that an *ars inveniendi* based on an algebraic calculus of concepts could be achieved. However, in his *Critique of Pure Reason* (1781) and in his *Logik* (1800), he developed a conception according to which an application of algebra to non-mathematical concepts would have no inventive power. Algebra is synthetic a priori, hence inventive and absolutely certain only on condition that its symbols stand for mathematical concepts. The latter are the only concepts whose objects can

be exhibited a priori in intuition, which gives algebraic proofs heuristic advantages and freedom from error. Kant's separation of logic from mathematics was counterbalanced by his rejection of the conception of a logic of the cognitive faculties that he had originally favoured. His mature view was that pure logic, as opposed to transcendental logic, is a formal science - a view not lightly to be dismissed.

Logic in the 19th century

The nineteenth century was one of the most active periods for logic in Western philosophy. It is regarded foremost as being the first time logic became 'symbolic' and 'mathematical'.

There was tremendous diversity and conflict in logic in this period - indeed there were substantial debates over whether there even is a subject called 'formal logic' and over what the most basic logical forms were. There was an explicit discussion in the early part of the century of whether logic should be extensional or intensional, opinion eventually settling on a purely extensional conception. By the end of the century, many of these debates had been resolved or had withered away, and the most widespread conception and practice of logic coalesced in the early twentieth century into a view we now identify with the works of Frege, Russell and Whitehead.

The nineteenth century brought, for the first time, from Boole and Frege, distinct proposals on how to symbolize logic that were both extensively developed and had widespread influence. Boole is correctly regarded as the father of modern symbolic logic. Frege shared two concerns of many nineteenth-century mathematicians - avoiding incorrect derivations and providing rigorous and clear foundations for the infinitesimal and derivative calculus - and therefore sought to develop a very clear notion of mathematical 'proof'. His notation has not been taken up but his influence, especially on the move towards symbolization, has been considerable.

De Morgan was the first logician extensively and symbolically to discuss the logic of relations. However, a systematic algebraic notation for relations was provided only later by Peirce, and developed also by Schröder.

1 Major movements and themes

Among the main topics in nineteenth-century logic were (1) the purpose or scope of logic, (2) the extent to which logic can usefully be symbolized or diagrammed, (3) the organization or codification of basic and derivative logical principles, such as in an axiomatization, (4) the relationship of logic to mathematics, (5) the relationship of types of logic, such as deductive and inductive, to each other, and to other ideal forms of reasoning, such as the scientific method, (6) how far logic should depart from the account of quantification in Aristotle's theory of the categorical syllogism, (7) the relationship of types of deductive logic, especially of categorical to propositional logic (usually called 'hypothetical logic' in the nineteenth century), and (8) the extent to which logic needs to treat relations in a special way.

There was little discussion of modal logics; of what we now call 'deviant' logic, such as discussions of nonstandard connectives (including the non-material conditional); or of the relationship of logic and natural language. There was an explicit discussion only in the early part of the nineteenth century (and in Schröder 1890-1905, vol. 1) of whether logic should be 'extensional' or 'intensional', opinion eventually settling on a purely extensional conception. Extensional logic treats terms only according to the concrete entities to which they refer; intensional logic treats terms according to their 'meaning', variously called intension, comprehension or connotation (see Intensional logics §1). C.I. Lewis (1918) advanced the thesis that the extensive symbolic development of logic required this extensional conception.

An already existing English (nominalistic) penchant for a logic of individual, concrete things was further solidified in works by Whately, Boole, Mill, De Morgan, Venn and Peirce; W.S. Jevons (1864) is unusual for his intensional theory of logic. German logic, owing to its often-noted idealist tendencies, had traditionally gravitated towards the approach that logic deals with concepts, not with 'things'. But works by Hermann Grassmann (1844) and Schröder (1877, and the monumental *Vorlesungen* of 1890-1905) had reversed this course. The works of Frege fall squarely within the older German intensional tradition, but this feature was virtually ignored by his English popularizers, such as Russell, and was later conflated with the firmly extensionalist, set-theoretic views of Dedekind and Cantor that arose contemporaneously in mathematics.

2 Purpose and scope of logic

Early modern philosophy, from the Renaissance to the late eighteenth century, had bequeathed numerous candidates for what was to be identified as the purpose or goal of 'logic'. The Renaissance Reform movement in logic, begun by Ramus and continuing through the Port-Royal logicians, modified and simplified the Aristotelian

conception of logic, and augmented it with a study of 'method' - which included inductive logic, for example. The English textbook movement, associated with works by figures such as Isaac Watts in the eighteenth, and Richard Whately and J.S. Mill in the nineteenth centuries, adopted standard Reformist topics, but were less interested in a philosophical theory of logic than in improving the reasoning of their student-readers. (Many twentieth-century textbooks unwittingly follow the Reformist topics and the pedagogical approach.)

Several issues in the very characterization of logic itself emerge. Was logic to cover all forms of reasoning, or only deductive reasoning? Was logic to be a theoretical account of the patterns of valid inference, or a practical, 'how-to' manual to help readers reason better or identify the faulty reasoning of others? The Reform and English-textbook traditions included treatments of deductive and inductive logic, together with other types of reasoning (analogy, causation, or scientific reasoning). This broad scope, together with an overriding pedagogical purpose, usually kept writing at a fairly superficial level, simply summarizing earlier views. The influential and subtle text of Richard Whately (1826) and the popular text of Mill (1843) fall squarely within this tradition. Even Augustus De Morgan (1847) treated 'the Calculus of Inference, Necessary and Probable'. The works of George Boole and Charles S. Peirce are also devoted to both deductive and inductive logics. (Only Peirce seems to have had a fully integrated and original theory of reasoning of all sorts; other authors simply followed the Reform syllabus.) Presumably because of a long-standing interest in a priori sentences and forms of inference going back to Leibniz, German logic was always focused exclusively on deductive logic. This included authors as diverse as Kant, Moritz Drobisch, Ernst Schröder and Frege.

Kant's views had considerable impact on German logic in the early nineteenth century and sharpened the tension between traditional, narrower conceptions of logic and a 'psychological' logic about the way humans must reason (see Kant 1800). Kant's conception of logic as the science of a priori judgments of all sorts, popularized by William Hamilton, led many English writers (Boole, Alexander Bain, Mill) to speak of the 'laws of thought'. In Germany, psychological theories and philosophical theories of logic were more thoroughly mixed by Wilhelm Wundt, Wilhelm Schuppe, Otto Külpe and - under the additional influence of Hegel - Christoff Sigwart and R.H. Lotze (and F.H. Bradley and B. Bosanquet) and many other psychologist-philosophers. These unholy mixtures brought fulminations from Frege that have been widely repeated in the twentieth century, often to suggest a fatal empirical taint to all of nineteenth-century logic. They are, however, rather 'laws' in the sense of how human beings 'must' (Kant) or 'should' (Peirce) reason; this is at worst a transcendental or normative theory of judgment and reasoning, rather than being simply empirical psychology.

Georg Hegel (1812) attacked what had been the often underdescribed guiding concept of most previous theories of logic, namely the idea of 'logical form', arguing that the distinction between 'form' and 'content' (of judgments or thoughts) was illegitimate. His own conception of logic defies simple summary, but vastly extended the Kantian conception. The extensions and critiques of Kant and Hegel drove early nineteenth-century German logic away from traditional logic. German logic as a philosophical discipline survived in the works of several anti-Kantian (and anti-Hegelian) logicians, among them Solomon Maimon, Moritz Drobisch (1838) and Bernard Bolzano, and was renewed through the later historical reappraisal of Leibniz and Aristotle by F.A. Trendelenburg (1847-67). Its true resurrection was, however, almost entirely due to professional mathematicians - Schröder and Frege, then Hilbert - who had little understanding of, or sympathy with, traditional philosophical logic.

3 Logic and mathematics: Boole

The idea of an 'algebra of logic' is a very old one, going back at least to observations by Jakob Bernoulli in 1685 (see Logic in the 17th and 18th centuries), with developed theories in unpublished manuscripts by Leibniz, and in published works by Lambert, Ploucquet, Euler and Grassmann (1844). George Boole then could modestly be credited only with the 'rediscovery' of the algebra of logic (1847, 1854). (Boole was apparently unaware of all these precedents, but was perhaps influenced by English views that were creeping towards a notion of an 'abstract' algebra, such as George Peacock's.) Nevertheless, his was an extensional theory of logic, was more developed than previous theories, occurred at a time when logic was ripe for a new and more mathematical approach and so had a sustained impact (direct or indirect) on all later symbolic theories (except Frege's). Boole is for these reasons correctly counted as the founder of modern symbolic logic.

However, Boole's logic had four features that were widely perceived as shortcomings. First, it had no account of relations. C.S. Peirce (1867-90) merged Boole's theory with De Morgan's work on relations to develop the

‘algebra of relations’ (see §5 below). Second, Boole treated propositional logic as a different interpretation of terms (as classes of ‘occasions’ or of ‘times’, rather than of concrete things). This reduction seemed unproblematic to Booleans but became suspect as Hugh MacColl (in a series of articles, ‘The Calculus of Equivalent Statements’, 1877-80) and Frege drew attention to what we now think of as propositional logic. Third, particular statements (using ‘Some… ’, that is, *I* or *O* propositions) were enduringly problematic, and eventually pointed the way towards the generally inadequate handling of quantification by Booleans. Boole would indicate that some *A*’s are *B*’s by writing $A = \mathrm{v}B$, where ‘v’ can be thought of as an operator that forms an arbitrary non-empty subset. Peirce and Schröder eventually introduced quantifier-like class operators, Π and Σ, to form classes with, respectively, all individuals and some individuals having a given logical attribute. The intersection of two classes, which we indicate by $A \cap B$, might then be written as $\Pi i \; Ai \times Bi$ - the class of all i’s that are both *A* and *B* - as well as by the simpler $A \times B$.

Finally, Boole’s symbol, ‘ $+$’, as described unambiguously in his more influential work of 1854, which can mean class union or propositional disjunction, was notoriously non-inclusive: ‘ $A + B$’ is interpretable only when *A* and *B* are mutually exclusive. Boole was not without his reasons for this troublesome requirement - it greatly simplifies the calculation of joint probabilities in inductive logic, permits an inverse operation to ‘ $+$’, and gets rids of the odd ‘ $1 + 1 = 1$’ (Lambert’s reasoning as well) - but as a feature of deductive logic, it was widely regarded as merely cumbersome. An inclusive interpretation was proposed by Jevons and Peirce in 1867, and this was widely adopted among Booleans. John Venn (1881) held on to the exclusive interpretation - presumably because of his joint concern for inductive logic.

Boole’s earlier work (1847) is in some ways a remarkable, subtle and little-understood work: it does not discuss ‘classes’ and instead gives a theory of what Boole calls ‘elective symbols’. These behave like subset-forming operators on the universe, 1.

Although Boole was paid homage by Peirce and Schröder as the founder (for Schröder, with Grassmann) of the algebra of logic, there are nevertheless respects in which they moved considerably beyond him. They thoroughly revised his handling of quantification, increasingly using quantifier-like operators. They were more interested in the algebra of relations, regarding the simple algebra of logic as somewhat trivial. And finally, they eventually moved away from Boole’s ‘equational’ style of presentation. That is, rather than using a primary symbol of class identity, ‘ $=$’, they used a symbol of class subsumption (‘subset’): Peirce’s ‘ $\prec$’ and Schröder’s ‘ $\subseteq$’.

A deeper difficulty was with Boole’s apparent reasoning why we should want to turn logic into algebra at all. He seems to have had the idea that doing so would make logic-learning easier and, since many people had algebraic symbol-manipulating abilities, logical reasoning could then rely upon these. He did not articulate deep or philosophical reasons why logic really ‘is’ an algebra; it was convenient and helpful to think this way. (In largely unpublished works of the early 1880s) Frege extensively criticized the underlying motivations for this connection between algebra and logic as superficial and philosophically casual.

The works of Peirce and Schröder in the late nineteenth century moved in a direction compatible with Frege’s critiques. Namely, they became less and less algebraic: no longer equational, and with the introduction of quantifiers, they contained variable-binding operators that disallow context-free algebraic-style substitutions. They also ceased pointing out parallels between logic and numerical algebra, and substantive uses of ‘l’ and ‘0’ disappeared.

4 Logic and mathematics: Frege

Frege speaks only briefly of his conception of the purpose of logic: it is to use a ‘*Begriffsschrift*’ (‘conceptual notation’ - Trendelenburg’s translation of a concept used in discussing Leibniz’s twin goals of a ‘*calculus ratiocinator*’ and a ‘*characteristica universalis*’). That is, Frege’s goal in his notation is to display in a perspicuous way the relationships between concepts and propositions (and presumably not merely those that are usefully similar to relationships in mathematics). The goal of the whole of logic is to demonstrate the correctness of deductions without gaps between premises and conclusions, using acknowledged formal and precise rules of inference. Frege’s focus seems initially to have been on determining the correctness (and hence non-synthetic, a priori nature) of mathematical proofs, rather than examining reasoning of all sorts, as had traditionally been the subject of logic. Logic before Frege had not devoted itself only, or even extensively, to reasoning in mathematics;

mathematicians were thought to be those least in need of help. Frege seems to have shared two concerns of many nineteenth-century mathematicians: avoiding incorrect derivations, like many faulty 'proofs' of the parallel postulate from other axioms and postulates in Euclidean geometry; and providing rigorous and clear foundations for the infinitesimal and derivative calculus ('analysis' - see Analysis, philosophical issues in §§1-2). His solution was, in essence, to develop a very clear notion of what counts as a mathematical 'proof'.

One might then guess that Frege was importantly involved in the axiomatic movements of the late nineteenth century, which first occurred in geometry (Hilbert and Veblen), then extended to the axiomatization of number theory (Peirce, Dedekind and Peano), set theory (Zermelo) and logic itself (R.A. Bernstein and Hilbert). This is not precisely correct, for Frege does not have a theory of axiomatics; certainly he had a general desire for care and precision, and developed reasons for this care and clarity, but his own demonstrations are neither more nor less likely to be flawed than those of Boole, Peirce, or Schröder, and are not axiomatic in any definite sense. Furthermore, Frege's notational system was so unusual and cumbersome that even Peano insisted that Frege's formulas be translated into his own notation before he would consider them. Our present notation for quantificational logic derives primarily from that of Whitehead and Russell's *Principia Mathematica*, which they in turn borrowed from Peano (see Peano 1973) - and these symbolisms were taken from original works by Peirce and Schröder's notational devices.

Frege's contribution lay elsewhere. He developed the first theory of quantification. The Boolean quantifiers of Peirce and Schröder were typically only class abstraction operators, with implicit rules given for their use. Frege also gave a very careful account of propositional logic (using notational devices for the material conditional and for negation) and made it the core of his theory - whereas for Aristotelians and Booleans, propositional logic was dependent on the logic of categorical statements, understood as a theory of classes. Furthermore, in later works, Frege was to use this theory to develop an account of the nature of numbers (1893, 1903) that was to have an enormous impact on Russell, and on the philosophy of mathematics. Finally, Frege contributed a great many concepts that have become part of the philosophy of logic: what we now call predicates and propositional functions; the use of 'functions' in logic; the distinction between sense and reference (see Sense and reference §§1-2); and many others.

Logic can be 'mathematical' in several distinct senses. It can simply use mathematical symbols and rules governing them; this is the method of Boole. It can be developed in the methodical, non-circular, clear way that was epitomized in Euclid's axioms and postulates for geometry, but had rarely been applied to other branches of mathematics, or to logic until the very late nineteenth century. It can be an independent discipline that is applied to mathematics, to give an analysis of concepts such as number or proof; this is closer to Frege's methodology. Finally, it can use mathematical techniques - of diagrams, demonstrations and proofs, and careful descriptions of mathematical structures. This is the modern and popular sense in which logic is sometimes said to be 'mathematical'. Peirce and Schröder might have understood and appreciated a claim, for example, that propositional logic defines a distributive lattice - a certain abstract algebraic structure - but Boole probably would not have understood such a claim and Frege would not have thought it insightful.

5 Relations

De Morgan is famous in logic for an often-repeated sentence he never wrote, roughly to the effect that all of Aristotelian logic was helpless to show the validity of the inference 'Since every horse is an animal, every head of a horse is the head of an animal'. The spirit is De Morgan's (except that he was surprisingly sympathetic to Aristotelian logic), but the example was Jevons'. The greatest logical and philosophical minds had long been aware of difficulties with relations, although they had often treated relational arguments as a marginal phenomenon. Plato and Aristotle were keenly aware of issues with regard to relations, and the medievals developed many theories of them (in supposition theory and in the theory of 'oblique' syllogisms - see Logic, medieval §§5, 7). Joachim Jung, the Port-Royal logicians and Leibniz were all aware of this literature - as were De Morgan and Peirce.

With the exception of the remarkable treatment of functions by Lambert in the mid-eighteenth century, De Morgan (1860) deserves credit for being the first logician extensively and symbolically to discuss the logic of relations. He briefly surveys the history of relations (starting with Aristotle), argues for the importance of relations in common thought, and for the centrality of relations in mathematics. He argues that traditional logic had only treated the

relations ‘identity’ and ‘non-identity’. De Morgan emphasizes the formal properties of identity that form the basis of inferential operations, namely transitivity and ‘convertibility’ (what we would now call symmetry or commutativity). He then proposes a notation for relations (or at least for identity), but demurs from a systematic algebraic notation, later to be provided by Peirce.

Peirce first made his proposals in a rambling essay of 1870. They were presented in a more succinct manner in papers of 1882 and 1883. He published his most successful axiomatic-like presentation of the non-relational and relational algebra of logic (extensively using the quantifier-like Σ and Π operators) in 1885 (see Peirce 1867-90). His logic of relations, unlike many logical proposals, was woven into his more general philosophical system, into his philosophy of mathematics, and into his theory of infinity. (Peirce, following a hint from De Morgan, defines infinite classes as those in which certain relational arguments are invalid, although they are valid for finite ones: this is the theory of the ‘transposed’ syllogism.) Peirce used his system extensively, proved a number of results in the logic of relations, invented a number of technical tools (such as ‘prenex’ form, in which all quantifiers occur first and with global scope), and suggested Church’s theorem: that there is no general mechanical routine for determining the validity or invalidity of an argument once relations and quantifiers are permitted.

In 1895, in the third volume of his *Vorlesungen*, Schröder presented the algebraic theory of relations in a lengthy but highly organized fashion, including the proofs of hundreds of theorems. He uses Peirce’s notation and theory, adding some notational variants - he is notably careful about the distinct universes of discourse (Boole’s ‘1’) for two- and higher-place relations, and, more fastidious still, proposes distinct empty classes (Boole’s ‘0’). Schröder uses Peirce’s quantifier-like Σ and Π expressions, but presents both relational logic (1895: vol. 3) and non-relational logic (1890: vol. 1) in a less axiomatic-like way than Peirce had in 1885. He connects the logic of relations to various matrix, numerical and geometric representations, sometimes using these as what we would now describe as ‘models’. Bertrand Russell in 1910, already familiar with Frege’s and especially Peano’s notations, pronounced the algebra of logic ‘cumbersome’.

The Peirce-Schröder notation and theory with relations was used, mainly in German-language logical work, until about 1920 (and in Skolem’s work for slightly longer). An overview is presented in English in Whitehead’s work of 1897, but otherwise no translation of Schröder’s *Vorlesungen* has ever appeared in English or French. (Although reprinted in 1966, it runs to over 2,000 pages and lacks an index.) Peirce’s work was buried in American mathematics journals of the 1870s and 1880s, at least until the publication of his *Collected Papers* from 1931 on. He published no book summarizing his logic. Consequently, since the 1920s, the algebra and logic of relations as a distinct field has been known only to scholars of the history of logic and mathematics, or to those fluent in German. Interestingly, no conclusive proof has ever been printed that the algebra of logic, particularly when enriched with its quantifier-like expressions or with relations, is inadequate in any technical respects. (Tarski claimed in 1941 that there were formulas of first-order predicate logic it could not express, but did not offer a complete demonstration.)

Frege stands curiously outside of the history of attempts to deal with the logic of relations. This is because he seems to have been completely unaware of the history of the logic of relations, and because his own theory was developed so independently of the other efforts to address the problem (that is, he was unaware of the works of De Morgan and Peirce, while Schröder’s work on relations appeared after Frege’s system was already formulated). His own theory, even in the early *Begriffsschrift* (1879), can obviously express everything that the algebraic theories could. Propositional functions (predicates) can have one or more argument places (1879: §10), but Frege does not draw attention to the difference between one-place functions (monadic predicates such as ‘is a cat’) and those with two or more places relational predicates, such as ‘is smaller than’). He seems unaware of or uninterested in the different logical and philosophical behaviour of properties and relations.

6 Main discoveries of nineteenth-century logic

In terms of successful influences, systematic symbolizations comprise the most obvious logical heritage of the nineteenth century. This is a tradition that clearly began with Boole, was modified and extended by Peirce (and to a lesser extent by Schröder), and then slightly reformed by Peano. Frege had little influence on notation now in common use, but considerable influence on the impetus to use symbolization. The linking of logic with mathematics had enormous impact on twentieth-century logic, but there are many distinct such links: the exact connections seen by De Morgan, Boole, Peirce and Frege are thoroughly different, ranging from the view that both

logic and mathematics can and should use similarly behaving symbolic systems, to views that mathematics 'is' logic (Frege, and perhaps Peano), or that logic 'is' mathematics (Boole, De Morgan, certainly Peirce). A further influence was the use of variable-binding operators, like those seen in mathematics (especially in the calculus). Finally, logic of both the Boolean and Fregean sort regarded a treatment of relational predicates as necessary, and not a marginal phenomenon - although this view is only implicit in Frege.

Both Peirce and Schröder used something quite similar to truth tables, a discovery usually credited to Wittgenstein. They also occasionally used models to show the independence of logical principles, a technique that was rediscovered and applied to logic in the 1920s; models themselves were suggested by the 'interpretations' and 'universes of discourse' of Boole and De Morgan. A clear notion of the 'completeness' of a logical system was absent, although they understood notions of independence and consistency; Peirce had some idea of decidability.

The value of studying nineteenth-century logic today, for other than its historical value, might include: algebraic - or at any rate 'mathematical' - structures inherent in logic as a theory of idealized thought or of the world; a reconsideration of the special structures and features to be found in the logic of relations; a perspective of the relationship of logic and mathematics that is closer to De Morgan's and Peirce's than to Frege's or Russell's; a return to an intensional conception of logic that once dominated logic and was rediscovered by Church in the 1950s and 1960s in the works of Frege; and conceptions of collective entities, and infinite collections, that retreat from the ornate and perplexing 'sets' of the twentieth century to something closer to the 'classes' of Boole, Peirce and Schröder - or perhaps to the concepts of Frege.

Fisch *et al.*, Bloomington, IN: Indiana University Press, 1982-.(The *Collected Writings* includes the more carefully edited versions - at

least of works up to 1886.)

Schröder, E. (1877) *Der Operationskreis des Logikkalküls*, Leipzig: Teubner.(Schröder's first, brief and elegant work on logic; shows familiarity with works by Boole and Grassmann, but not yet with works by Peirce or De Morgan, or with the theory of relations.)

Schröder, E. (1890-1905) *Vorlesungen über die Algebra der Logik (Lectures on the Algebra of Logic)*, Leipzig: Teubner, 3 vols; repr. New York: Chelsea, 1966.(The monumental *locus classicus* of the algebra of logic, including relations; a highly systematic work that totals thousands of pages and hundreds of theorems; unindexed, it remains untranslated and has probably been read in its entirety by only a handful of German-speaking readers. See Dipert (1990-1) for discussion.)

Styazhkin, N.I. (1964) trans. *History of Mathematical Logic from Leibniz to Peano*, Cambridge, MA, and London: MIT Press, 1969.(A briefer treatment of nineteenth-century logic than Kneale and Kneale (1962), but often more insightful and knowledgeable in its discussions of symbolisms, of German logic in the eighteenth and nineteenth centuries, and of Russian figures such as Poretskii.)

Trendelenburg, F.A. (1847-67) *Historische Beiträge zur Philosophie*, Berlin: Bethge.(Together with his *Logische Untersuchungen* and editions of Aristotle's *Prior Analytics*, this book began interest in the logics of Leibniz and Aristotle in the German-speaking world; probably read in part by Frege.)

Venn, J. (1881) *Symbolic Logic*, London: Macmillan, 2nd edn, 1894; repr. New York: Chelsea, 1979. (By the time it appeared, this work was unoriginal, but usefully summarized Boolean logic in a book-length form more readable than Boole's own works; the first Boolean 'textbook'.)

Whately, R. (1826) *Elements of Logic*, Delmar, NY: Scholars' Facsimiles and Reprints, 1975.(A highly intelligent, succinct, non-symbolic work that represents the high-water mark of the non-symbolic English 'logic textbook' tradition.)

Logic in the early 20th century

The creation of modern logic is one of the most stunning achievements of mathematics and philosophy in the twentieth century. Modern logic - sometimes called logistic, symbolic logic or mathematical logic - makes essential use of artificial symbolic languages.

Since Aristotle, logic has been a part of philosophy. Around 1850 the mathematician Boole began the modern development of symbolic logic. During the twentieth century, logic continued in philosophy departments, but it began to be seriously investigated and taught in mathematics departments as well. The most important examples of the latter were, from 1905 on, Hilbert at Göttingen and then, during the 1920s, Church at Princeton.

As the twentieth century began, there were several distinct logical traditions. Besides Aristotelian logic, there was an active tradition in algebraic logic initiated by Boole in the UK and continued by C.S. Peirce in the USA and Schröder in Germany. In Italy, Peano began in the Boolean tradition, but soon aimed higher: to express all major mathematical theorems in his symbolic logic. Finally, from 1879 to 1903, Frege consciously deviated from the Boolean tradition by creating a logic strong enough to construct the natural and real numbers. The Boole-Schröder tradition culminated in the work of Löwenheim (1915) and Skolem (1920) on the existence of a countable model for any first-order axiom system having a model.

Meanwhile, in 1900, Russell was strongly influenced by Peano's logical symbolism. Russell used this as the basis for his own logic of relations, which led to his logicism: pure mathematics is a part of logic. But his discovery of Russell's paradox in 1901 required him to build a new basis for logic. This culminated in his masterwork, Principia Mathematica, written with Whitehead, which offered the theory of types as a solution.

Hilbert came to logic from geometry, where models were used to prove consistency and independence results. He brought a strong concern with the axiomatic method and a rejection of the metaphysical goal of determining what numbers 'really' are. In his view, any objects that satisfied the axioms for numbers were *numbers. He rejected the genetic method, favoured by Frege and Russell, which emphasized constructing numbers rather than giving axioms for them. In his 1917 lectures Hilbert was the first to introduce first-order logic as an explicit subsystem of all of logic (which, for him, was the theory of types) without the infinitely long formulas found in Löwenheim. In 1923 Skolem, directly influenced by Löwenheim, also abandoned those formulas, and argued that first-order logic is all of logic.*

Influenced by Hilbert and Ackermann (1928), Gödel proved the completeness theorem for first-order logic (1929) as well as incompleteness theorems for arithmetic in first-order and higher-order logics (1931). These results were the true beginning of modern logic.

1 What is modern logic?

Modern logic crystallized gradually during the period 1850-1950. It was not created by any one person or school, but evolved from the work of several. We now recognize that the following features were needed for its mature development:

(a) There is a formal language whose symbols separate it from ordinary language.

(b) In the formal language, *L*, the syntax is clearly separated from the semantics. The syntax is like the grammar of a natural language, specifying which sequences of symbols (called 'formulas') are permissible. Meaning does not occur in the syntax but in the semantics. Thus logical concepts such as sentence, axiom, formal proof and consistency are part of the syntax. Concepts such as truth, satisfiability and definability are part of the semantics. Formal proofs can be checked effectively and do not depend on the meaning of the terms in them.

(c) Within the syntax of *L*, the logical symbols are clearly separated from the non-logical symbols. The logical symbols include connectives such as 'and', 'not', 'if…then…'. The meaning of the non-logical symbols changes with different interpretations, while that of the logical symbols does not. The non-logical symbols may include individual constants, which, in the semantics, are interpreted as specific individuals. There may also be function constants and relation constants, which are interpreted as specific functions and relations. Besides the logical and non-logical symbols, there are variables, which may be free or bound.

(d) The syntax gives a recursive definition for the formulas of *L*.

(e) There is a clear distinction between the object language *L*, in which our formulas occur, and the metalanguage, in which we speak about *L*. Within the metalanguage, we must define what truth means in *L*. Theorems in the metalanguage are called metatheorems.

(f) Usually there will be levels within our symbolic logic. The lowest level (called propositional logic) is that of the connectives ‘and’, ‘not’, and so on. The next level will have individual variables *x* and quantifiers (‘for all *x*’, ‘there exists an *x*’) over those variables. If that is the highest level, then we have first-order logic. But there may also be function variables (or relation variables) and quantifiers over them, giving second-order logic (see Second- and higher-order logics). In the simple theory of types, there are individual variables, function variables, variables for functions of functions, and so on, and this is sometimes called ω-order logic. We must decide which order our logic will have.

(g) We must also specify other matters. Will the semantics of our logic have only two truth-values, ‘true’ and ‘false’, as in traditional logic, or will it have three or more truth-values (see Many-valued logics)? Will our logic be ‘classical’ (in which the law of the excluded middle holds) or ‘intuitionistic’ (in which that law fails; see Intuitionism)? Will our logic be finitary (like all the logics discussed above) or will it be infinitary (that is, have infinitely long formulas, or have variable-binding operators that give the same effect, or have rules of inference with infinitely many premises; see Infinitary logics)?

(h) Finally, we must study the metatheory of *L*, that is, what general results can be proved, in the metalanguage, to be true of *L*. This includes the consistency and independence of the logical axioms for *L* as well as whether *L* is ‘complete’ (that is, whether every true sentence of *L* is provable in *L*).

2 Logic in 1900

In 1900 there were five main approaches to logic. The first of these was traditional Aristotelian logic, in which the syllogism was central. It had split into several branches, encompassing the idealist logic of Bradley and the pragmatist logic of Dewey. The remaining approaches differed from the first by using symbols in a fundamental way.

The second approach was that of Boole. In 1854 Boole had introduced a logical calculus, whose symbols were borrowed from mathematics, and given his calculus three interpretations: propositions, classes and probability. Around 1900, Boole’s active successors were Peirce and Schröder. During the 1880s Peirce had modified Boole’s logic by introducing quantifiers and relations. The second approach was regarded as trivial by certain Oxford logicians who espoused the traditional one (see Passmore 1968: 156, 240).

The third approach originated in Italy. There Peano began his work on logic (1888) within the Boolean tradition, influenced by Schröder (1877). To avoid confusing Schröder’s logical symbols ‘ $\cdot$’ and ‘ $+$’ (for ‘and’ and ‘or’, respectively) with the corresponding arithmetical symbols for addition and multiplication, Peano replaced them with his own, derived from Hermann Grassmann: ‘ $\cap$’ and ‘ $\cup$’. Peano retained a Boolean ambiguity by interpreting ‘ $\cap$’ and ‘ $\cup$’ not only as ‘and’ and ‘or’ between propositions but also as ‘intersection’ and ‘union’ of classes. (In 1906 Russell removed this ambiguity by keeping ‘ $\cap$’ and ‘ $\cup$’ for ‘intersection’ and ‘union’ while introducing a new symbol ‘ $\vee$’ for ‘or’ and using a dot for ‘and’; nevertheless, like Frege, he had no non-logical symbols and so did not satisfy requirement (c) above.) Peano went beyond the Boolean tradition by symbolizing much of mathematics.

The fourth approach, that of Frege, was isolated from the others. Frege proposed a second-order symbolic language for treating mathematics - particularly the real and complex numbers - in his *Begriffsschrift* (1879). There he replaced the traditional logical notions of subject and predicate by the more mathematical ones of function and argument. In the culmination of his work (*Grundgesetze der Arithmetik*, 1893 and 1903), he attempted to establish that all truths of arithmetic (but not geometry) can be proved from logic alone (see Logicism). To do so, he used a very strong logic, which in 1902 turned out to be inconsistent. No doubt his daunting two-dimensional symbolism partly accounts for his limited influence at the time. But Frege was also isolated by his explicit refusal to work in the Boolean tradition, as well as by his many innovations and his severe criticisms of other logicians.

The fifth approach to logic, that of Hilbert, was rooted in the foundations of geometry. In 1899 he gave axioms for Euclidean geometry that were purely formal, although not yet expressed in symbols. He proposed three main tasks for such an axiom system: establishing its consistency, independence and completeness. (At that time, 'completeness' was imprecise and required only that the axioms imply all known theorems of geometry.)

So at the turn of the century there was no unified tradition in logic and no common view of what logic is and what its goals are; at the same time, it was generally agreed that there is only one correct logic. This fragmented situation continued until at least 1930 (although the Boole-Schröder tradition was strong until the 1920s), when the theory of types became increasingly important. After 1930, first-order logic gradually replaced the theory of types.

3 The algebraic tradition of Boole and Schröder

During the 1890s Schröder continued the Boolean tradition (see §2 above). Schröder's logic began with his 'identical calculus' or lattice theory (1890: 161); it was related to a calculus of classes, one of domains and one of propositions. In 1895, his calculus of relations elaborated that of Peirce.

Although a critic of Frege, Schröder too regarded arithmetic as a part of deductive logic (1890: v) and later went beyond Frege's version of logicism by stating that 'I consider pure Mathematics to be only one branch of general Logic' (1898: 46).

The Boole-Schröder tradition culminated in the work of Löwenheim and Skolem. Löwenheim's most important paper (1915), on Schröder's calculus of relations, distinguished between first-order and second-order logic while retaining elements of infinitary logic (see §10 below). Löwenheim's semantic theorem was that if a first-order formula is true in all countable domains, then it is true in all domains. Löwenheim was well aware that this result failed in his full logic, which was a kind of infinitary second-order logic.

In 1920 Skolem extended Löwenheim's theorem, and in this form it is known as the 'Löwenheim-Skolem theorem': if a countable set of first-order formulas has a model, it has a countable model. This was the first major metatheorem for first-order logic.

4 Peano's tradition

The most important of Peano's logical accomplishments was to invent a clear symbolism. Much of it - such as $\in$ for class membership and $\supset$ for material implication - continues today, thanks to its adoption by Russell. By contrast, the logical symbolisms of Frege and Schröder are all but extinct.

In 1891 Peano believed that he could express any logical relation by using seven primitive symbols: $\in$ ('is'), $=$ ('is equal'), $\supset$ ('implies'), $\cap$ ('and'), $\cup$ ('or'), $-$ ('not') and $\wedge$ ('absurd'). He was mistaken, as Frege remarked. Partly under Frege's influence, Peano used nine kinds of primitive symbol in 1897: the old signs $\in$, $\supset$, $\cap$, $-$, together with the signs *K* ('class'), (x, y) ('ordered pair'), $=_{\mathrm{Df}}$ ('definition'), parentheses and variables. Yet both Frege and Peano accepted the principle of comprehension (that is, every predicate determines the class of those things satisfying the predicate), which eventually led to the paradoxes.

Peano tried to render mathematics completely unambiguous by expressing it in his symbolism. He first used his symbolism in geometry (1888), next in his postulates for the natural numbers (1889), and then he applied it to differential equations (1890). He assembled a group of Italian collaborators to create the encyclopedic *Formulaire de mathématiques* (1894-1908), which aimed to symbolize all major mathematical theorems.

Among those collaborators was Alessandro Padoa, who investigated the undefinability of a term from other terms in a given axiom system (1901). Padoa emphasized that the notion 'definable' was not absolute but depended on the particular axiom system and its primitive symbols. This insight was overlooked when the paradoxes of definability, such as Richard's paradox, were discovered soon afterward (see Paradoxes of set and property §6).

5 Russell's response to Peano and Frege

In 1900, before he discovered the paradoxes, Russell adopted Peano's symbolism and used it to develop his own logic of relations. Russell was particularly impressed by Peano's distinction between the membership relation $\in$ and the relation $\supset$ construed as inclusion. Peano did not distinguish, however, between the implication $p \supset q$ and the inference 'From the proposition *p* infer the proposition *q*', although this distinction had already been made by

Frege (1879). The deduction theorem - a metatheorem showing the correct relation between the two - was only proved by Tarski in about 1921.

For Russell, symbolic logic had three parts: the calculi of propositions, of classes and of relations. In the *Principles of Mathematics*, he gave primacy to the propositional calculus over the calculus of classes (1903: 12), and also proposed his logicism, which went beyond Frege's by including geometry and parts of mechanics: all mathematical concepts are definable from the basic concepts of logic, and all mathematical theorems are provable from the axioms of logic.

In 1903, after finishing the *Principles*, Russell shifted from an analysis of logic in the spirit of Peano to one in the spirit of Frege. Peano had given the universal quantifier only in the form $\phi x \supset_x \psi x$, that is, 'For every *x*, ϕx implies ψx'. Russell introduced a new notation for an idea that he took from Frege: $(x)\phi x$, that is, 'For every *x*, ϕx'. Likewise, Peano had been able to express an existential quantifier only in the form $\exists a$, that is, 'The class *a* is non-empty'. Russell introduced a Fregean existential quantifier: $(\exists x)\phi x$, that is, 'There is an *x* such that ϕx'. Russell's notation later became standard. It had the virtue of disentangling quantifiers from the quantifier-free part of a formula and of disentangling logical formulas from the notion of class. Finally, Russell adopted Frege's assertion sign, '$\vdash$'. Thus, for Russell, $\vdash (x)\phi x$ meant 'It is true that $(x)\phi x$'. (Nowadays $\vdash$ does not mean 'it is true that' but rather, 'it is provable that', and indicates a theorem of logic; see Church (1956: 82).)

6 Hilbert, the geometric tradition and the American postulate theorists

Hilbert's interest in logic stemmed from his devotion to the axiomatic method, which he first exploited to give a definitive form to the axioms of Euclidean geometry in 1899. Here he continued the geometric tradition by using models to establish the consistency and independence of his axioms. Yet he distanced himself from the traditional philosophical concern with what points or numbers 'really' are by treating them as unspecified 'things', defined only by the axioms. As long as the 'things' satisfied the axioms, he insisted, it did not matter if they were points, lines and planes, or tables, chairs and mugs. In accordance with requirement (b) in §1 above, the syntax was separated clearly from the semantics.

At that time Hilbert corresponded with Frege on the foundations of geometry. Frege held the traditional view that the geometric axioms express intuitions, while Hilbert supported the modern view that an axiom system at most determines the 'things' mentioned up to isomorphism (see Nagel 1939). Frege insisted that the only way to prove the consistency of an axiom system was to give a model, while Hilbert believed that the consistency of a system yields the existence of a model in which it is 'true' (see Frege 1980: 39). Brouwer disputed Hilbert's claim in 1929. Around 1930, Gödel proved this claim for first-order logic, but, using incompleteness, refuted it for second-order logic (see §9).

From 1900 until 1940, the axiomatic method, as formulated by Hilbert and Peano, was used by a group of mathematicians sometimes called the American postulate theorists (see Scanlan 1991) to axiomatize a variety of mathematical systems - including the complex numbers, Boolean algebra, and fields - and to prove the consistency and independence of the axioms. This group included Huntington, Veblen and E.H. Moore. In 1902, while giving an axiomatization for the real numbers, Huntington isolated the idea that this system has, up to isomorphism, only one model. Such a system is 'categorical' (to use the name that Veblen gave it in 1904). A year later, Huntington conjectured that every categorical system *S* is deductively complete, that is, every sentence expressible in *S* is provable or refutable in *S*. It was not until Gödel's incompleteness theorems that Huntington was proved wrong. Moreover, in first-order logic, any system having an infinite model is not categorical (see §8).

7 *Principia Mathematica*

Between 1902 and 1913 Russell and Whitehead wrote *Principia Mathematica* (1910-13), which aimed to give strong evidence for logicism by axiomatizing logic (via the theory of types) and deducing much of pure mathematics from it. In doing so, Russell was particularly concerned to avoid the paradoxes of logic. He also shared with Peano a desire to minimize the number of axioms and primitive concepts.

Principia Mathematica strongly influenced the development of logic, but most of that influence did not come until the 1920s. When its second edition appeared in 1925, Russell considered the most important improvement to logic to be the reduction by Sheffer of the primitive concepts of propositional logic from two ('or' and 'not') to one

('neither… nor') and the reduction by Nicod of its axioms from five to one. (Ironically, later logical research hardly used such reductions.) But in that edition Russell did not mention a more important advance made by Wiener (1914) and known to Russell: the definition of ordered pair (and hence of relation) in terms of classes.

Not everyone accepted the theory of types. Veblen argued that 'formal logic has to be taken over by mathematicians…. There does not exist an adequate logic at the present time, and unless the mathematicians create one, no one else is likely to do so' (1925: 141).

Already in the *Principles* (1903: §17) Russell believed it impossible to establish the independence of one axiom of logic from the others. In *Principia Mathematica*, Whitehead and Russell retained this conviction (1910: 95). For Russell, as for Frege, one cannot stand outside of logic, and so it is not surprising that *Principia Mathematica* lacked a metalanguage. This notion of metalanguage originated with Hilbert (1922), from whom it was adopted by Tarski (1930) and Carnap (1934). It was natural when a system of logic was viewed as simply another mathematical system. (Russell (1922) independently considered levels of language.) Nowadays, the most important theorems of logic are metatheorems, that is, theorems in the metalanguage about the system of logic, and they involve the sort of notions that Hilbert used in his theorems about geometry: consistency, independence and completeness.

8 The emergence of first-order logic

By 1955, first-order logic was dominant among logicians who were mathematicians (though the theory of types remained important among philosophers). However, first-order logic was slow in coming. It first clearly emerged as a 'subsystem' of logic in Hilbert's lectures of 1917, published in Hilbert and Ackermann (1928). (Löwenheim had separated a subsystem of logic from his full system in 1915, but his subsystem allowed quantifiers to be expanded into infinitely long formulas, and so was richer than first-order logic, in which all formulas have finite length.)

Hilbert, unlike Löwenheim, was very careful to specify his syntax, and gave, for the first time, a recursive definition of first-order formula (see (d) in §1 above). Hilbert also stated axioms for first-order logic. While he had borrowed his axioms for propositional logic from *Principia Mathematica*, first-order logic was his own. Moreover, he differed from Russell by posing the metamathematical questions of the consistency, independence and completeness of his axioms. He proved the consistency of both propositional and first-order logic, but was unable to answer the other questions. Hilbert wanted to give axiomatizations for various theories within logic, whereas Russell wanted a strong logic in which to deduce those theories from his logical axioms. Hilbert's long-term goal was to prove the consistency of all of classical mathematics by finitary means (see Hilbert's programme and formalism.)

In 1917 Hilbert persuaded Bernays to work with him on logic. Bernays' first results (1918, published only in 1926) established the independence and completeness of propositional logic. Meanwhile, Post had independently found and published them (1921).

Also in 1917, Hilbert emphasized the '*Entscheidungsproblem*': to find a decision procedure for every mathematical problem. Within the Schröderian tradition, decision procedures had already been studied by Löwenheim (1915), who solved the *Entscheidungsproblem* for monadic predicates within first-order logic, a solution improved by Skolem (1919). Within Hilbert's school, Bernays gave a decision procedure for propositional logic in 1918, and in 1928 argued that the *Entscheidungsproblem* was the central problem of logic (see Proof theory §2). Work on the *Entscheidungsproblem* consisted of finding a decision procedure for more and more complicated classes of first-order sentences in prenex normal form (that is, consisting of a quantifier-free matrix preceded by a string of quantifiers), where the complexity of the class was measured by the number of quantifiers in the prefix.

Meanwhile, in 1923, Skolem abandoned the infinitely long formulas adopted from Schröder and Löwenheim, and began working explicitly in first-order logic. Skolem made the radical proposal that the membership relation '$\in$' of set theory be treated, not as a part of logic in the way that Peano and Russell had done, but like any other relation (that is, as a non-logical symbol). In logic, such relations could be given various interpretations, and so should '$\in$'. This proposal resulted in the so-called 'Skolem paradox' of first-order logic: set theory has a countable model although it contains uncountable sets (see Paradoxes of set and property §9).

In France, Herbrand (1930) made a major contribution to the relation between propositional logic and first-order logic.

9 The definitive metatheorems: Gödel on completeness and incompleteness

The most important person influenced by Hilbert's logic was Gödel, whose doctoral dissertation (1929) solved Hilbert and Ackermann's problem of showing, for countable languages, the completeness of first-order logic: every valid first-order formula is provable. In fact, Gödel proved the stronger result that every consistent set of first-order formulas has a model (1929).

When Gödel's completeness theorem was published in 1930, he included as a corollary the 'compactness theorem': a set of first-order formulas has a model if every finite subset has a model. The importance of this theorem was only appreciated later by Maltsev (1936) and Henkin (1947) when they introduced uncountable languages.

Even more important were Gödel's incompleteness theorems (1931). His first incompleteness theorem stated that if a 'decidable' set Σ of formulas implies the axioms for the natural numbers with addition and multiplication, then there is a sentence in the language of Σ that is neither provable nor refutable. (Here 'decidable' means that there is a mechanical procedure for determining whether a formula is in Σ.) The second incompleteness theorem stated that such an axiom system Σ cannot prove its own consistency (see Gödel's theorems).

The incompleteness theorems were devastating. They refuted Russell's logicism by showing that there are true mathematical sentences which cannot be proved in the theory of types. Likewise, they refuted Hilbert's programme, since the consistency of number theory cannot be established except by a stronger theory. Church soon established that there is no decision procedure for first-order logic. Finally, the incompleteness theorems led to attempts, by Carnap and Zermelo, to circumvent them by introducing an infinitary logic (see §10).

10 The prehistory of infinitary logic

Peirce and Schröder treated quantifiers in a way that differs from the modern one. If we fix a finite set with *n* elements $a_1, a_2, \ldots, a_n$ as our universe *D* of discourse and let *Px* mean that *x* has the property *P*, then in *D* we can express 'All *x* have property *P*' by ' Pa_1 and Pa_2 and… and Pa_n'. If *D* is infinite and its elements are $a_1, a_2, \ldots, a_n, \ldots$, then Peirce and Schröder still treat 'All *x* have property *P*' as equivalent to ' Pa_1 and Pa_2 and… and Pa_n and… '. (An analogous statement holds in *D* for 'Some *x* has *P*' and ' Pa_1 or Pa_2 or… or Pa_n or… '.) Thus a quantifier could be expanded as an infinite conjunction or disjunction. This was the beginning of an infinitary logic, but one that was not yet formulated as a distinct kind of logic.

Here we see two distinct ways of treating quantifiers: (1) 'For all *x*, *Px*' and (2) the infinitely long conjunction ' Pa_1 and Pa_2 and… and Pa_n and… '. Frege, Peano and Russell used quantifiers only in the first way. By contrast, Peirce and Schröder used both ways interchangeably. Hilbert (1905) was influenced by Schröder to define quantifiers in the second way when the universe *D* was the natural numbers. In his mature work (1923), Hilbert still viewed quantifiers as going beyond the finitary.

Meanwhile, within the Schröderian tradition, Löwenheim used not only such infinitely long conjunctions and disjunctions but also infinite strings of quantifiers, in his paper proving Löwenheim's theorem. Skolem continued to use this infinitary logic when in 1920 he extended Löwenheim's theorem to a countable set of first-order formulas, but by 1923 he abandoned infinitary logic in favour of first-order logic.

Infinitary logic arose, independently, in Zermelo's paper (1931) reacting against first-order logic and specifically against Skolem's argument that there is a countable model for set theory (see Paradoxes of set and property §9). Zermelo formulated a strong infinitary logic in which, he hoped, the Löwenheim-Skolem theorem was false. Soon he had a second reason to propose an infinitary logic, namely to avoid Gödel's incompleteness theorems and to have every valid sentence be provable. But Zermelo's logic was adopted by no one.

Hilbert, Tarski and Zermelo each formulated a different version of an infinitary rule of inference, now known as the ω-rule. (Influenced by Hilbert and Tarski, Carnap also used the ω-rule.) This rule requires the language of logic to have infinitely many names, one for each natural number *n*. If a formula $\phi(a_n)$ has been proved for the

name a_n of each natural number *n*, the ω-rule infers 'For every *x*, $\phi(x)$'. Without the ω-rule, an axiomatization of the natural numbers could be ω-inconsistent, that is, prove $\phi(a_n)$ for each natural number *n* but also prove 'There is some *x* such that not $\phi(x)$'. Unlike Carnap, Hilbert and Zermelo, all of whom supported this rule, Tarski was occasionally sceptical of it.

Only in 1955 were infinitely long formulas accepted as a legitimate part of mathematical logic - thanks to Henkin, Tarski and Karp - in apparent ignorance of earlier work on such formulas by Zermelo and others. By this time, first-order logic was firmly established as the logical framework for mathematics, and those infinitary formulas were considered within various extensions of first-order logic. A different kind of extension was proposed by Mostowski (1957): generalized quantifiers. One such quantifier was 'there exist uncountably many'. For that quantifier, Mostowski asked if it is possible to prove a completeness theorem analogous to that for first-order logic. Later the answer turned out to be 'yes'.

11 A glance past Gödel: recursion theory, model theory, set theory

Modern logic began with Gödel's completeness and incompleteness theorems. Today they are the goal of most introductory logic courses. From his incompleteness theorems, recursion theory emerged during the 1930s, when the notion of 'computable' was made precise by the Gödel-Herbrand notion of recursive function and, equivalently, by Turing machines (see Computability theory).

Model theory emerged as a distinct part of logic around 1950, although its first important result (Löwenheim's theorem) dates back to 1915. One fundamental notion - relational structure - was already vaguely present in Hilbert (1899). A relational structure is an ordered pair consisting of a set and a family of relations on that set; such structures include groups, fields and Boolean algebras, but not topologies. Model theory began to develop into its modern form through the discovery that the strong completeness theorem for first-order logic (that is, any consistent set of first-order sentences has a model) implies results about structures. Connected with this was Henkin's use of languages with uncountably many symbols (1947) and Tarski's classification (1952) of structures up to 'elementary equivalence' (that is, being indistinguishable in first-order logic).

Meanwhile, set theory developed much closer ties with logic. In 1938 Gödel used first-order logic to prove the important result that if the usual axioms of set theory are consistent, they remain so when the axiom of choice and the generalized continuum hypothesis are assumed (see Axiom of choice; Set theory). Gödel's idea was to consider, not all sets, but only those sets first-order definable from sets of previous levels (see Constructible universe). And in 1963 first-order logic was essential to Cohen's proof that the axiom of choice and the generalized continuum hypothesis are independent of the usual axioms of set theory (see Forcing).

12 Coda: what is modern logic?

Until about 1850, it was fairly easy to say what logic was. Today it is much harder, although classical first-order logic remains dominant. After 1920, many-valued logics (that is, those having three or more truth-values) were investigated by Post and Łukasiewicz. Likewise, modal logic was seriously studied, thanks to C.I. Lewis (1918; see Modal logic). And during the 1950s infinitary logic crystallized. Finally, there are now many specialized logics (see, for example, Quantum logic).

During the 1970s first-order logic was characterized by 'Lindström's theorem': first-order logic is the strongest logic that contains propositional logic and for which the compactness theorem and the Löwenheim-Skolem theorem hold. Thus any logic which extends first-order logic must violate the compactness theorem or the Löwenheim-Skolem theorem. An idea of the wide range of modern logic can be obtained by consulting Barwise (1977), Barwise and Feferman (1985), and Gabbay and Guenthner (1983-9).

Logic machines and diagrams

By 'logical diagrams' we generally mean any two-dimensional representations of logical relationships, such as of class inclusion or consequence. One usually also means representations using non-typographical symbols or geometric figures. Such diagrams were first used in the seventeenth and eighteenth centuries, but gained wide currency only in the nineteenth; the best known are the Euler and Venn diagrams. It is an open question whether logical diagrams are useful only as elementary pedagogical devices, or have implications for advanced logical research.

The conception of an organism, the mind, or of the universe as 'machine' was not really attractive and useful until machines were widespread, complex and able to perform interesting tasks. This occurred first in the late Renaissance, and initiated ways of thinking that dominated the seventeenth and eighteenth centuries. It was also becoming evident that machines could be used to perform some complex, repetitive or difficult tasks more reliably or faster than human beings.

The very idea of machines that can perform 'symbolic' tasks, such as mathematical, logical or, eventually, linguistic ones required first a symbolism. For this reason, the idea of computers for mathematical or logical tasks, and systems of mathematical and logical notation, are strongly intertwined: one must have efficient ways of feeding information into a machine, and interpreting the results.

1 Logical notation

Among the higher-level purposes for any symbolism in logic are: to abbreviate or simplify the writing or the display; to highlight strictly logical relationships without non-logical distractions (roughly Leibniz's *lingua philosophica* or his *characteristica universalis*); or to facilitate insights into the ways these representations may be manipulated, such as through inference (roughly Leibniz's *calculus ratiocinator*, 'calculus of reason').

It is customary to divide notational devices between those that represent substantive (often called 'categorematic') terms and those that represent logical relations or properties (often called 'syncategorematic' terms). Symbols for categorematic terms can stand for determinate individual or abstract entities, such as '*c*' for Julius Caesar, '*a*' for the class of apples, '*A*' for the property of being an apple, or '*P*' for the sentence 'All apples are red'. Symbols may also stand for arbitrary, non-specific examples of such terms, such as in the example, 'Consider a class of objects, *c*, or a proposition, *P*'. These are usually called variables, schemata or place-holders.

Perhaps the earliest use of abbreviations for categorematic terms was by Aristotle, who occasionally used single letters to stand for non-specific categorical terms in his *Prior Analytics*. While many later Aristotelian logicians occasionally used letters to represent categorical terms, only in the late medieval and early modern period do we find any use of special symbols, other than Latin or other 'natural language' expressions, for syncategorematic (logical) notions. One of the first of these was Luis Vives' use in the first half of the sixteenth century of a V-shaped symbol to represent term inclusion:

$$(1)\quad \begin{array}{c} A \\ \mathrm{v} \\ B \\ \\ \\ \end{array} \qquad\qquad (2)\quad \begin{array}{c} A \\ \mathrm{v} \\ B \\ \mathrm{v} \\ C \end{array}$$

Diagram (1) represents that the term *A* is wholly included in *B*. ('All *A*'s are *B*'s.') Diagram (2) indicates that *A* is included in *B*, *B* is included in *C*, and, implicitly, *A* is (thus) included in *C*.

2 Philosophies of logical notation

The final goal of any logical notation is presumably to best allow one to carry out and communicate logical work. With Vives' and later notations, we begin to see four intermediate goals concerning how logical notation can achieve this final goal:

(1) The use of linear linguistic symbols, primarily deriving from natural language or other common usage (such as

mathematics) and used mainly as abbreviations. Polish notation is an extreme example of this phenomenon, using, for example, '*Kpq*' for $p \& q$. (We might also include here mnemonic aids: for example, 'K' for Konjunktion - alas, only for speakers of some languages.)
(2) The use of special symbols chosen mainly for their distinctness from natural language symbols.
(3) The use of special symbols or notations that are 'ideographic' (Styazhkin) or 'iconic' (Peirce): properties of the symbols themselves are intended to mirror attributes of the represented logical relationship.
(4) Two- (or higher) dimensional notational systems using elements of 1, 2, or 3; that is, diagrams.

Observe that (1) and (4) may clash: achieving (1) may aid writers, printers and proof-readers, while achieving (4) may aid readers of the notational system. Similarly, (1) obviously clashes with (2) and perhaps with (3), if the natural language symbols are not fortuitously iconic ('and' is a non-palindrome although conjunction is symmetric).

Leibniz was fascinated by ideographic notations (owing to a passing interest in Chinese pictograms), but it was C.S. Peirce who first seems to have consciously chosen and systematically discussed symbolisms according to their iconic characteristics. One of his points is that to represent a non-symmetric logical relationship, one should use a visually non-symmetric symbol. That is, since $A \supset B$ does not always have the same truth-conditions as $B \supset A$, then one should use an asymmetric symbol, such as $\supset$, $>$ or his own $-\!\!<$. Such considerations have been at work implicitly in the choice of virtually all logical symbols for conjunction, disjunction and so on (except those chosen in line with (1), such as '*K*' and 'Čamp;').

Various symbols that came into widespread use in algebra and calculus in the sixteenth, seventeenth and eighteenth centuries, such as '$=$' and '$+$', involved similar (implicit) considerations, and hark back to suggestions by Viète, Descartes and Leibniz. The 'algebra of logic', such as we see in works by Leibniz, Lambert and, especially, Boole, borrows symbols already in use from algebraic notation (and thus is a species of goal (1)), but capitalizes upon their original iconic character in mathematics - goal (3). Both Peirce and Schröder later gave up the use of symbols for logical constants that were simply borrowed from algebra, using considerations from both (2) and (3), while preserving the algebraic (substitutional) character of many operations. (See Logic in the 19th century.)

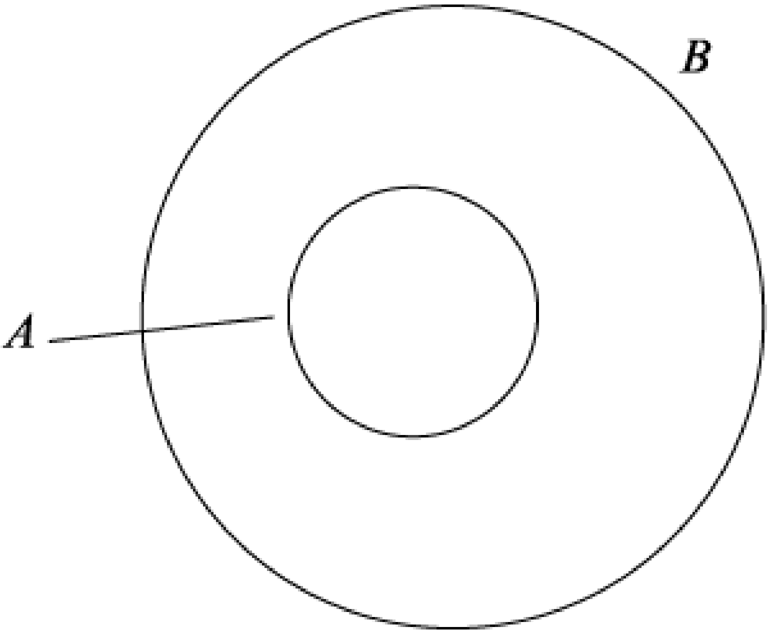
While the use of parentheses as indicating priority or scope of operations is of long-standing mathematical use, many of the other symbols now in use derive from the work of Giuseppe Peano. (These were sometimes inspired by earlier works in the algebra of logic, and were later injected into the mainstream of logic by Russell, Whitehead and others.) These symbols were primarily chosen by Peano according to consideration (2) - distinctiveness - and according to their suggestive, or etymological character: '$\in$' for the Greek 'esti'; '$\supset$', a backward 'C', for the converse of 'containment', and so on. He seems not to have considered the 'iconic' arguments of Leibniz and Peirce, and forcefully rejected the more original two-dimensional proposals of Frege.

3 Euler and Venn diagrams

The two most widely used styles of logical diagrams are usually referred to as 'Euler' and as 'Venn' diagrams. Both are primarily used to represent inclusion or subsumption of classes or terms in Aristotelian logic. There are two main distinctions between these diagrams. Euler's method involves placing circles of various sizes in various patterns; Venn's uses circles of uniform size in fixed positions, which are then modified by other markings. Euler's method does not have any unambiguous way of indicating the existence of individuals satisfying a certain description, other than implicitly by the spacing of the circles. Venn has such techniques.

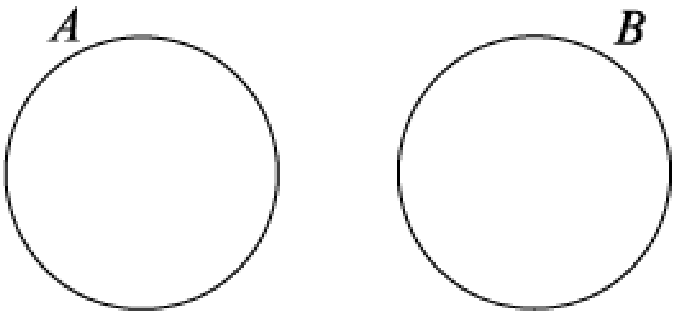
Leonhard Euler developed his method in his *Lettres à une Princesse d'Allemagne sur divers sujets de physique et de philosophie (Letters to a German Princess on Various Subjects of Physics and Philosophy)* in 1761, published in 1772 (see Logic in the 17th and 18th centuries §5). The method was later adapted by Gergonne, Maimon and others, and was frequently given an intensional as well as the original extensional interpretation. The following diagrams exhibit the method:

Euler Diagrams



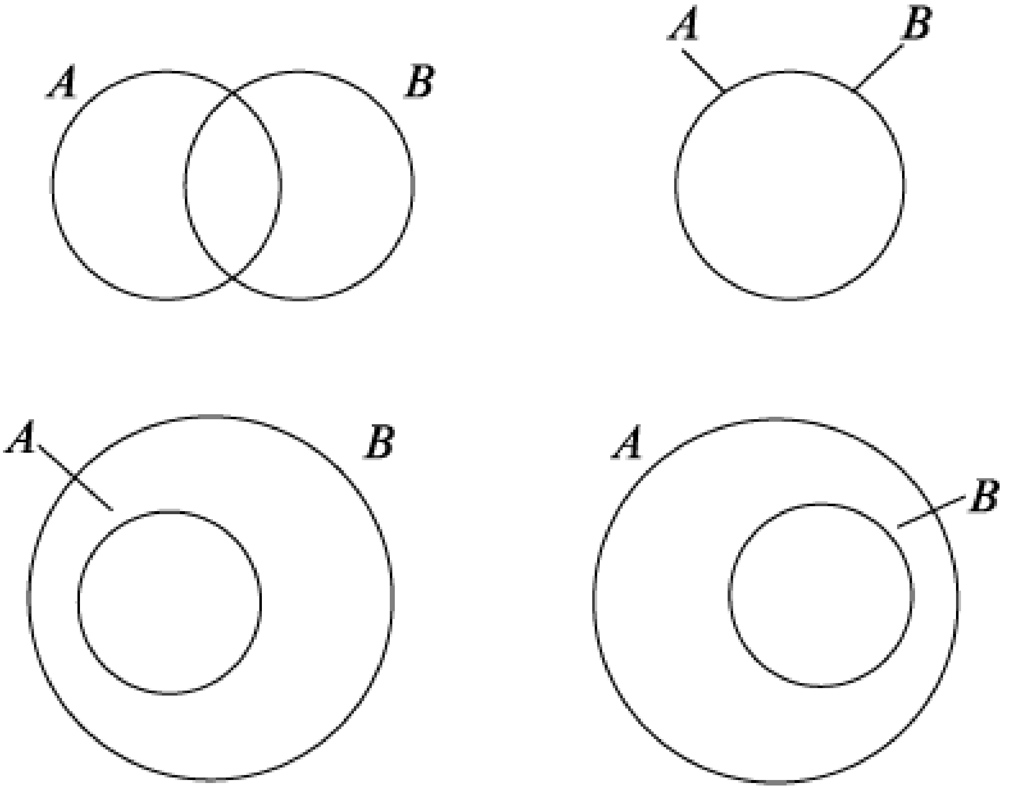
1. *A*-statement

Intensional reading: all the properties in concept *A* are included in the concept of *B*; all *A*'s are *B*'s. Extensional reading: all of the *A*-type things fall in the class of *B*-type things; all *A*'s are *B*'s.



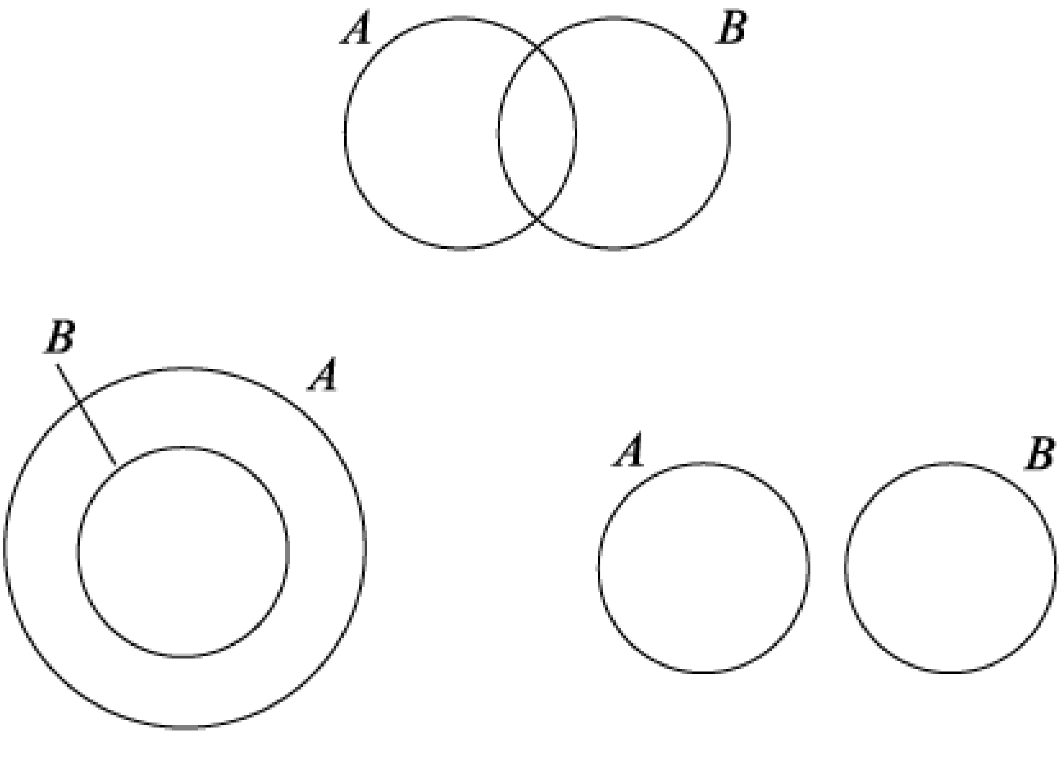
2. *E*-statement

Intensional reading: concepts *A* and *B* share no properties. Extensional reading: no individual is both *A* and *B*.



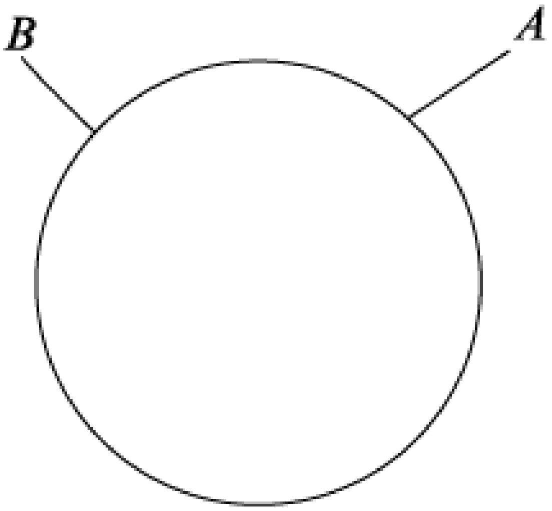
3. *I*-statement

Intensional reading: concepts *A* and *B* share some properties. Extensional reading: there are individuals that are both *A* and *B*. (Alternatives classified by Gergonne.)



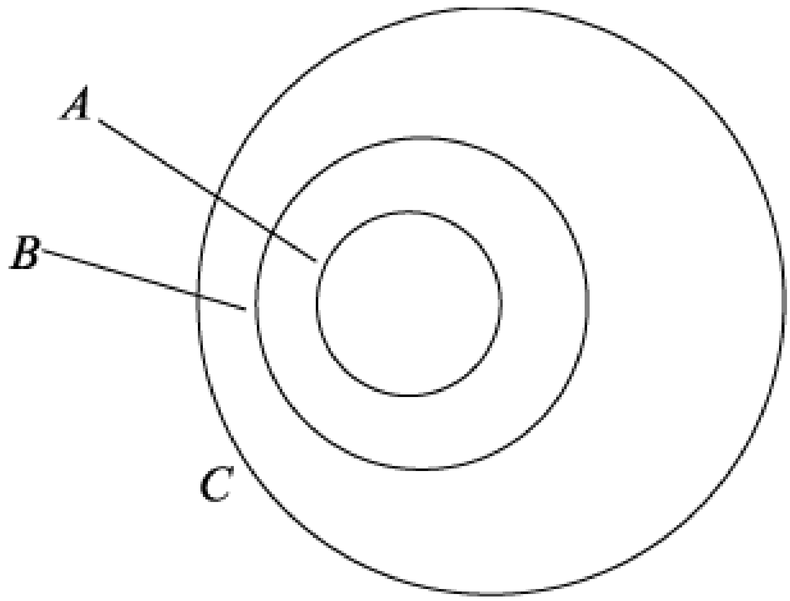
4. *O*-statement

Intensional reading: there are properties in concept *A* that are not in concept *B*. Extensional reading: there are individuals that are *A* but not *B*. (Alternatives classified by Gergonne.)



5. Identity

Intensional reading: *A* and *B* share all their properties. Extensional reading: the individuals that are *A* are the same as those that are *B*.

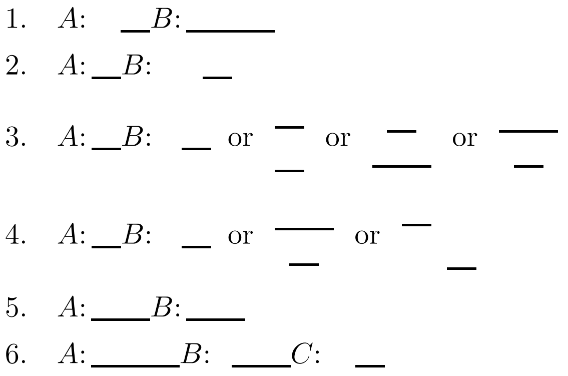


6. 'Barbara' syllogism

All *A*'s are *B*'s, all *B*'s are *C*'s, so all *A*'s are *C*'s, extensionally interpreted.

Observe that the intensional and extensional reading of the *A*-statement are 'reversed': to say that all apples are fruit is to say that all components of the concept of fruit (come from a plant, contain a seed, are edible, and so on) are included in the more numerous components of the concept of 'apple'. Observe also that there is an overlap in the alternative diagrams of the *O*- and *A*-statements (made explicit by Gergonne). Such an observation led to William Hamilton's (and George Bentham's) notorious doctrine of the 'quantification of the predicate', although similar ideas were common in the eighteenth and nineteenth centuries: we should distinguish between 'All *A*'s are some *B*'s' (1, 3, and 4) and 'All *A*'s are all *B*'s' (5).

The method of using movable, usually intensionally interpreted, circles was first suggested in published works by J.C. Sturm in 1661, and in unpublished writings of Leibniz. Contemporaneous with Euler, J.H. Lambert (1764) developed a method of using overlapping lines, also extensionally interpreted:

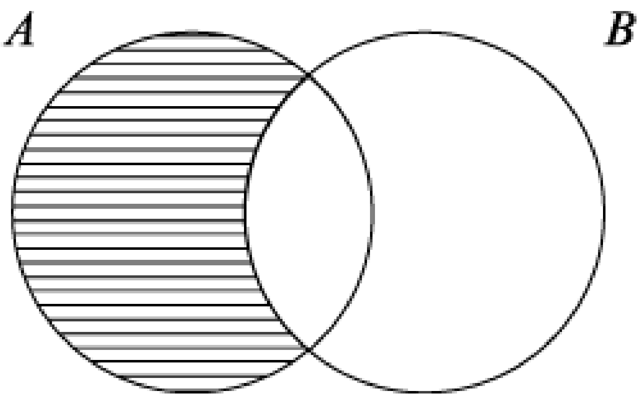


This method had also been anticipated by Leibniz in unpublished notes. In fact, the uses of circles or lines iconically to represent logical relationships reappears so often, and apparently independently, in the history of logic since the seventeenth century that one can count the idea - like that of an ‘algebra’ of logic - as more or less obvious to anyone who thought much about logic.

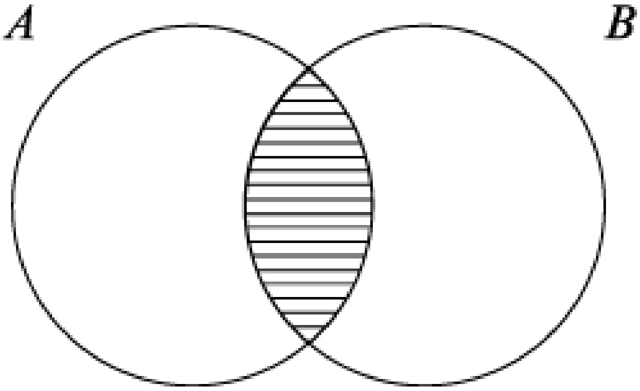
Venn diagrams are usually credited to John Venn in an article of 1880, and then more extensively developed in his *Symbolic Logic* (1881). This method was anticipated by similarly extensional diagrams of the German logician Moritz Drobisch in his 1838 *Neue Darstellung der Logik (New Conception of Logic)* (see Logic in the 19th century §2). After a decline in usage in the early twentieth century, Venn diagrams have reappeared in many introductory logic texts of the second half of the twentieth century.

Venn Diagrams

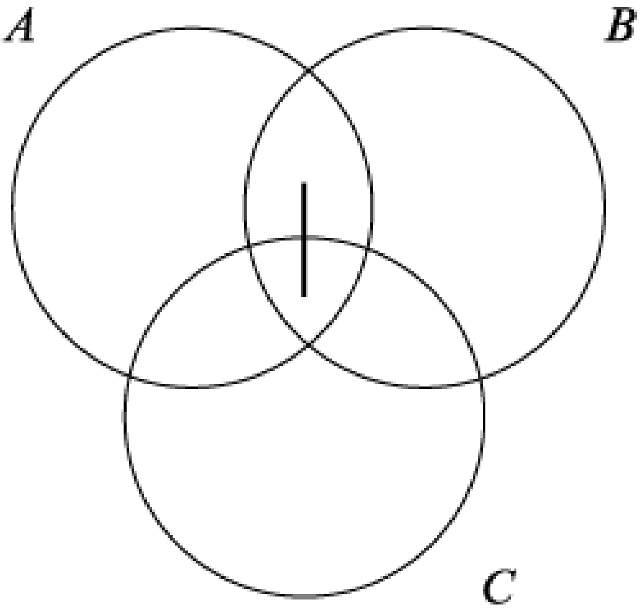
Statements are interpreted extensionally: points in an area indicate individuals having certain properties. What properties individuals have (or what classes they belong to) is indicated by inclusion in a circle: if they lack a property, they fall outside of that circle. The non-existence of individuals with a certain description is indicated by shading the corresponding area. The existence of an individual with certain properties (or lacking certain properties) is shown by an ‘*x*’ if it is fully determinate what properties it has, or by a line across two or more areas if it is not determinate.



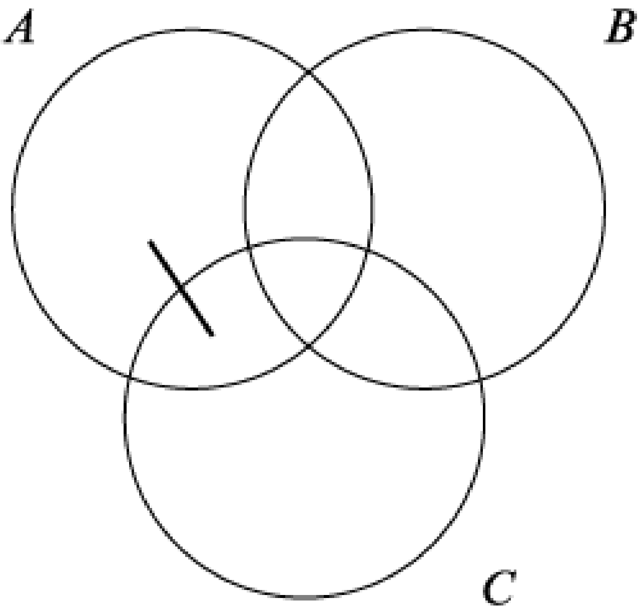
All *A*’s are *B*’s.



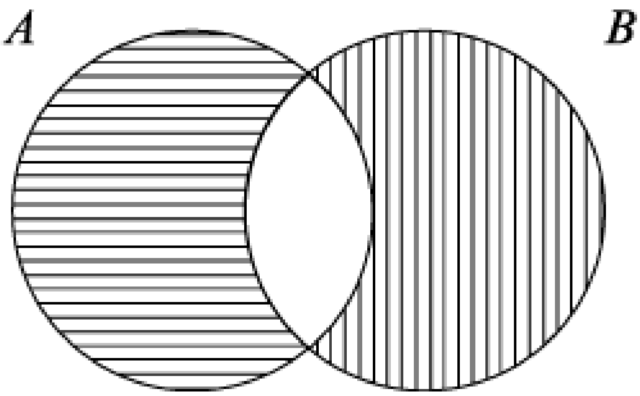
No *A*’s are *B*’s.



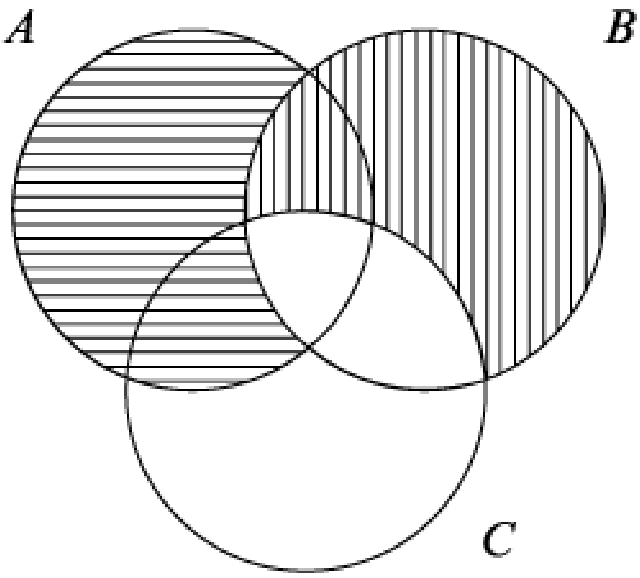
Some *A*’s are *B*’s: maybe they are *C*’s, maybe not.



Some *A*’s are not *B*’s.



All *A*’s are *B*’s, and all *B*’s are *A*’s.



All *A*’s are *B*’s.

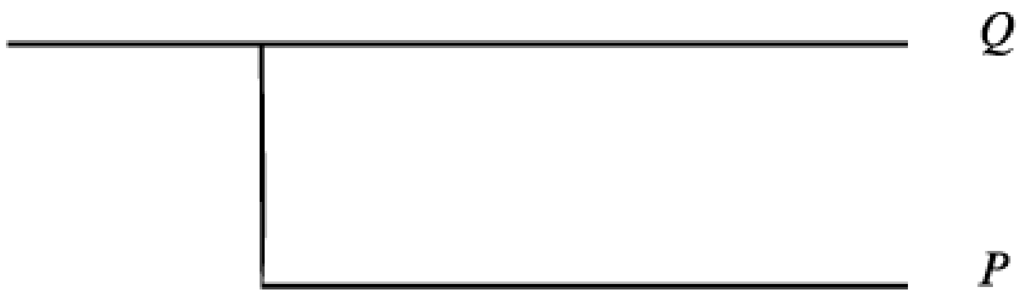
All *B*’s are *C*’s.

So, all *A*’s are *C*’s.

The details of this interpretation are suggested by Drobisch and Venn, but carefully stated by Schröder in his *Vorlesungen* (1890-1905). Other diagrammatic methods in the nineteenth century included a system of triangles used by William Hamilton, and the use of matrices or tables by Allan Marquand and Lewis Carroll. Still other methods in the twentieth century include Veitch diagrams (see Veitch 1952) and Karnaugh maps. All of these methods, with the exceptions of the methods of Peirce and Frege, are versatile enough only for Aristotelian (monadic predicate) or propositional logic, and not for full first-order predicate logic.

4 Frege’s *Begriffsschrift*

Gottlob Frege’s notation, the famous ‘*Begriffsschrift*’ (‘conceptual notation’; see Frege, G.), is partly diagrammatic. He draws the material conditional in a two-dimensional way, writing $P \supset Q$ as follows.



The only specifically two-dimensional feature seems to be intended to highlight a feature of *modus ponens*, the main rule of inference using the material conditional - namely, the condition (antecedent) 'drops away'. The use of the negation line and the descending vertical line (negation stroke) in the material conditional was clearly intended to suggest the interpretation of the material conditional $P \supset Q$ as $-P \vee Q$. Frege stubbornly stuck to his own notational system throughout his life, in spite of the difficulty it presented for typographers, criticism from Peano (and Schröder), its non-iconic and ahistorical character, and the fact that even admirers such as Russell and, later, Wittgenstein and Hilbert, never adopted it. Nevertheless, something of what motivated Frege, namely a concern for displaying features of *inferences* in a two-dimensional way, rather than the logical content or 'sense' of individual sentences, leads one to helpful formats for displaying mathematical or logical demonstrations ('proofs'), such as the later 'natural deduction' methods of Gerhard Gentzen. (See Natural deduction, tableau and sequent systems §1).

5 Peirce's existential graphs and conceptual graphs

There is little suggestion in any of these proposals that diagrams have any point much beyond a heuristic value, being 'suggestive', and helping to learn logic at the introductory level. No one seems to have proposed that diagrams have a serious, advanced use for professional logicians, or represent more accurately an underlying metaphysical reality. A notable exception are Charles S. Peirce's 'existential graphs' (see Peirce, C.S. §8). Peirce, a historian of logic and a careful reader of his contemporaries, knew about the diagrammatic methods of Euler, Lambert and Venn. In the 1890s he developed three sophisticated systems of logical diagrams that he called the alpha, beta and gamma existential graphs. (His choice of 'graph' for these diagrams is somewhat unfortunate, since they are not graphs in the technical sense first used by J.J. Sylvester in 1878, now in wide use, and which Peirce would have known.) Both graph theory and Peirce's graphs were inspired, interestingly, by chemical diagrams. Furthermore, other chemical metaphors occur in both the works of Frege ('saturated') and Peirce. Alpha graphs are similar to Venn diagrams, and can be used for either categorical logic or for what we would call propositional logic. Beta graphs can be used to represent any quantified relational sentence or set of sentences, and are thus a fully general method for diagramming sentences in first-order predicate logic - the first such method in the history of logic. Gamma graphs are used for the representation of modal statements. All three graph systems are 'iconic' in a sense of which Peirce was explicitly aware; he was also interested in enhancing their calculational usefulness for producing new inferences ('forward inference'), or for identifying the correctness of given conclusions from given premises ('backward inference').

Furthermore, the graphs are not just employed for their usefulness in some narrow sense, but grew out of views he had developed much earlier: his 'philosophy of notation' of 1885. This was the first statement of what became a large, developed theory of signs (his semiotics) and a philosophy of mind - of thoughts themselves, at least in all a priori disciplines, being 'diagrammatic'. (Peirce's views are reminiscent of the better-known 'picture theory' of Wittgenstein's *Tractatus*.) Peirce believed that our visual notations should match or facilitate, as much as possible, the best possible mental diagrams, and this means that the notational system should exhibit useful logical relationships. In earlier, algebraic-style writings, this was developed within a standard linear sequence of symbols; in later writings, he seems to have believed that two-dimensional representations were required for the properly 'iconic' display of some logical relationships, especially once relations are introduced.

Peirce's ideas about existential graphs were not much noticed until the 1960s, and have not had a noticeable impact, except as a curiosity, until the 1980s. In computer science and artificial intelligence, Peirce's ideas have been put forward as 'conceptual graphs' (by John Sowa 1991) and have found a wider audience. This is in part because there had existed in artificial intelligence a prior interest in using 'semantic networks' for representations of the meaning of natural language sentences. In cognitive science and learning theory, there is also a resurgence of interest in optimizing the display of information to native human cognitive processes, and thus of presenting complex relational information through visual images.

6 Early logic machines and mechanical machines for Aristotelian logic

Interestingly, the very first speculations about or design of machines that performed conceptual tasks - one hesitates to call them exactly 'logic' - were inspired not by arithmetic calculators, but by a strange mixture of medieval magic and theology. This was the fantastic *Ars Magna* ('Great Art' or 'Technique') of the Spanish

(Majorcan) mystic and tinkerer Ramon Llull (§2). Llull was interested in the way the various concepts (God, evil,…) could be combined. To this end, he designed various notations, as well as ‘machines’ that used labelled, movable, concentric wheels to show these combinations. Although his views were respected by a variety of later thinkers such as Bruno and Swift, his greatest impact was on the development of the combinatoric theory by Pascal and Leibniz in the late seventeenth century.

Not surprisingly, the thought occurred to Pascal, Leibniz and others of using the combinatoric wheels of Llull, but labelling them with numerals, and gearing them so that they could do various arithmetic calculations. There are thus two conceptual steps that were necessary to produce the idea of logic machines. First, one must be able to think of machines as being able to perform calculations - to compute. (This in turn requires a notation and machines of some complexity and accuracy, that is, many finely machined parts.) Second, one must be able to think of reasoning and inference as a type of ‘mechanical’ calculation: this was the contribution of Llull, refined by Pascal and Leibniz, and explicitly stated by Leibniz as the *calculus ratiocinator*.

Both Pascal and Leibniz designed and had constructed for them geared arithmetic calculators. Leibniz also proposed, perhaps for the first time, the idea of a logic machine, and left some suggestions about how this might be done - but never developed precise designs nor constructed an actual machine.

The first reasonably successful logic machine was probably the eighteenth-century ‘Demonstrator’ of Charles Stanhope. It used a notation system that anticipated William Hamilton’s variant of Aristotelian logic, and could also perform elementary arithmetic and probabilistic calculations. The Demonstrator was constructed from a block into which two moving slides were inserted, one of grey wood and the other of red glass; the positions of these slides served as the input premises and the extent of their overlap, visible in a small square in the block, represented the strongest possible conclusion validly derivable from these premises. That is, the Demonstrator was a ‘forward inference’ machine that actually generated a conclusion, rather than determining the validity or invalidity of a given conclusion with given premises. The use of the Demonstrator for deductive logic was limited to categorical logic with two premises.

The high-water mark of mechanical logic machines was reached by William Stanley Jevons’ machine, usually called the ‘Logical Piano’, from the appearance of its keyboard. While restricted to categorical logic, this 1870 machine represented a vast improvement over Stanhope’s Demonstrator, both logically and mechanically. Consisting of a keyboard for inputting premises and, above it, connected by pulleys and levers, a display of terms, the Jevons machine could accommodate up to four terms, and thus arguments with more than two premises (‘sorites’), with designs for machines with up to ten terms. It could also handle ‘or’ terms in either subject or predicate terms (understood inclusively), such as ‘All fruit are apples or oranges’. It used a Boolean equational system, and thus could also be considered the first algebra machine, since it essentially solved systems of equations. Like the Demonstrator, one did not input a conclusion to determine its validity given a set of input premises, but instead the machine output all valid conclusions with the input premises in the logical system.

7 Electrical machines and the twentieth century

A slight improvement in Jevons’ design was made by Allan Marquand, who had been a logic student of Peirce and later became a professor of art history at Princeton. He called his a ‘New Logical Machine’ (1885). It was not logically more sophisticated than Jevons’ machine, but had a better display, consisting of a grid of rotary indicators, looking something like a water or gas meter. Marquand also sketched designs for the first electrical logic machine, using relays and switches. (The very first electrical circuit diagram to be used for logic or interpreted logically was proposed in a letter from Peirce to Marquand.) Nothing really came of these proposals, and they, like Babbage’s ideas for a general-purpose symbolic manipulator, were historical curiosities that had no discernible influence on electrical and electronic computers of the mid- and late twentieth century.

While there were a number of authors who developed mechanical logic machines in the late nineteenth and early twentieth centuries, mostly in imitation of Jevons’ device, the collapse of the Aristotelian approach to logic made most of these techniques obsolete. Indeed, the logic of Frege, Russell and Whitehead, which permits quantifiers and relations, and which we know as predicate logic, makes the very idea of logic machines a daunting task. Expressions no longer consist of certain restricted combinations of terms. Furthermore, as Church’s theorem was later to suggest, it may be that certain logical tasks in this framework are mechanically impossible. Similarly, the

idea of allowing a machine to reason whatever it can from given premises - forward inference, imitative of human reasoning - becomes extremely problematic. Designs for electrical logic machines appeared again shortly after the Second World War, first with work by two students of W.V. Quine, William Burkhart and Theodore Kalin in 1947, a number of machines in the late 1940s and early 1950s, and culminating in the 'Logic Theory Machine' of Allen Newell and Herbert Simon in 1956. (During the Second World War, Claude Shannon had developed his influential logical interpretation of electrical circuitry, thus rediscovering the observations of Peirce and Marquand.) Significantly, all these machines were restricted to propositional logic, and thus also fell far short of the expressivity and complexity of quantificational logic. Logic machines and computer programs in the twentieth century have been largely focused on 'backward' inference: confirming that a given conclusion does, or does not, validly follow from a given set of premises.

The history of logic machines grew distinct, after the early days of Leibniz and Pascal, from the history of machines to perform arithmetic calculations. There were enormous economic pressures to develop numerical calculators (for accounting and also for navigational tables), and few incentives to develop machines that reasoned using logic. Another line of development that was initially distinct from that of logic machines was the development of general purpose, programmable computers. Most early calculating and logic machines of all sorts were one-purpose and 'hard-wired'. Charles Babbage is the originator of the conception of a general-purpose 'computer', but the approach was rediscovered in the twentieth century, and intensively developed in mechanical, electrical and electronic implementations during and after the Second World War. In this approach, we build a 'computer' so that it can be 'programmed' to perform any task of symbolic manipulation that is capable of algorithmic description. Although the idea of such a general-purpose symbol-manipulator is an old one, going back to Babbage in the early nineteenth century, no one seems to have thought of programming such machines to perform logical tasks until Turing, nor succeeded until the Logic Theory Machine. Today, virtually all computational projects in logic are performed on general-purpose computers, and thus in an important sense the idea of dedicated 'logic machines' is obsolete. It is the software (programming), not the hardware, that is designed to perform logical tasks. Starting in the 1960s and accelerating rapidly in the 1970s and 1980s, a large amount of computer software (including 'mechanical theorem provers') now exists that performs a variety of logical tasks in various logical systems, including first- and second-order predicate logic, 'deviant' logics and modal logics.

Logic of ethical discourse

Logic, as a discipline, is largely concerned with discovering principles and methods for evaluating the evidential strength between the premises and conclusions of arguments. Because the meanings of terms (and the concepts they express) that occur in arguments bear importantly on questions about evidential relations, much of the work on the topic of logic and ethics has been preoccupied with questions about the meanings of moral terms and concepts, and with the correct linguistic analysis of sentences that contain them. Taking logic to include issues about meaning (which has commonly been done by those who refer to the so-called 'logic of moral discourse') is to construe the subject broadly. But the field of logic is often construed quite narrowly to refer to the study of formal languages whose syntax, axioms and inference rules are sufficiently determinate to allow decisions about what counts as the theorem in such a language. On the narrower understanding of logic, the intersection of logic and ethics has mainly to do with work in deontic logic. This article takes up issues concerning the intersection of ethics and logic broadly construed. The intersection of logic and ethics concerns questions about the nature of moral reasoning. Some philosophers have attempted to deduce substantive moral conclusions from factual statements - in particular, to derive 'ought' statements from 'is' statements. If one can successfully carry out such deductions, then moral reasoning is guided properly by consideration of nonmoral facts from which moral conclusions can be derived. However, the eighteenth-century philosopher David Hume is often credited with arguing that no such deductions are correct; that there is a gap between factual 'is' statements and moral 'ought' statements. There is disagreement over whether or not Hume's negative claim is correct; but even if it is, there may still be logical features of moral concepts that impose constraints on proper moral reasoning.

One such widely discussed constraint is the thesis of universalizability, according to which relevantly similar cases must receive the same moral evaluation. One implication of this thesis is that moral judgments about particular cases entail universal moral principles and so some have argued that all correct moral reasoning must be understood in terms of subsuming particular cases under general moral principles. Although many philosophers have accepted this subsumptive model of moral reasoning, it has come under attack by philosophers who argue that proper moral reasoning is primarily a matter of sensitively discerning the morally relevant details of a case under consideration and rendering a moral judgment about it without the guidance of principles.

1 The is/ought question and Hume's law

In a famous passage (1739/40), David Hume complains that writers on morality often move almost 'imperceptibly' from factual statements about what is the case to conclusions about what ought to be the case, and do so without adequately explaining or justifying this transition from 'is' to 'ought' (see Hume, D. §4). Hume then demands that 'a reason should be given, for what seems altogether inconceivable, how this new relation can be a deduction from others, which are entirely different from it' (1739/40: 469). What has come to be called 'Hume's law' is the claim that the sort of 'deduction' Hume calls for cannot be negotiated successfully, hence the maxim, 'No "ought" from an "is"'. (Whether Hume actually held this maxim is the subject of some scholarly debate.) The alleged is/ought gap is often used to support the claim that ethics is logically autonomous in the sense that no moral statements can be correctly inferred from any set of nonmoral premises (a thesis which, as we shall see in §4, is much stronger than Hume's law).

Although questions about the relation between 'is' statements and (moral) 'ought' statements has generated a great deal of philosophical discussion, the problems and issues they involve are part of a more general issue about the relation between factual statements and normative statements (in particular moral statements of all types, including statements about value or goodness) (see Moral realism). However, most of what follows will focus on the is/ought issue.

To understand the debate surrounding the alleged is/ought gap, more must be said about Hume's law and its philosophical presuppositions. The law presupposes that a useful distinction can be made between factual ('is') statements and moral (specifically, 'ought') statements, though, of course, many moral statements (such as 'Keeping one's promises is right' and 'Lying for personal gain is something one ought not do') contain the word 'is'. If we take for granted an understanding of specifically moral uses of such terms as 'right', 'good' and 'ought', then, intuitively, moral statements are statements in which some moral term like 'right', 'good' or 'ought' is

predicated of some object of evaluation (whether or not the statement contains the word 'is'). Nonmoral statements are all those statements in which moral terms are not predicated of some object of evaluation. Factual statements represent a proper subset of nonmoral statements which purport to assert the existence of, or describe (using vocabulary other than terms like 'right', 'good' and 'ought'), things, events, states of affairs or whatever. Now the root idea behind Hume's law is that it is not possible to infer validly an 'ought' statement from a set of factual statements, since, as Hume puts it, 'this *ought*, or *ought not*, expresses some new relation or affirmation' (1739/40: 469; original emphasis) not contained in the premises. In order, that is, for a moral 'ought' statement to be inferred validly from a set of factual statements, the latter would have to entail the former; but there is no such entailment relation since factual claims do not include any moral terms and, in particular, they do not include any use of the term 'ought'. So, for example, from the factual claim of the form (F) one cannot infer validly a moral claim of the form (M):

(F) All or most people do, or would upon reflection, approve of such and such type of action being performed.
(M) Such and such type of action ought to be performed.

Obviously, one way to refute Hume's law and overcome the alleged is/ought gap would be to include among the set of factual premises what can be called 'moral bridge principles' that would link moral terms with nonmoral terms and thus allow for the valid deduction of moral conclusions. So, for instance, if we add to (F) a bridge principle of the form (B), then statements of the form (M) can be inferred validly by canons of ordinary logic:

(B) If all or most people do, or would upon reflection, approve of such and such type of action, then actions of that type ought to be performed.

Granted, (B) together with (F) jointly entail (M), but this does not disprove Hume's law unless a case can be made for claiming that (B) is a nonmoral, factual claim. And this in turn depends on how we interpret it. Traditionally (and this is another presupposition of the philosophical debate over Hume's law) any claim (if true) is either an analytic truth, in which case it is true simply in virtue of the meanings of its constituent terms, or a synthetic truth, in which case its truth does not depend simply on the meanings of its constituent terms (see Analyticity). If construed properly as a synthetic truth, then any instance of (B) has the status of a substantive moral claim, and hence adding it to an appropriate instance of (F) to derive an instance of (M) will not count as a violation of Hume's law - in fact such a derivation tends to confirm that law. However, if we can find an appropriate moral bridge principle that is construed properly as an analytic truth, then, since in general such truths simply report conceptual or linguistic truths about language, such a principle would simply describe a nonmoral fact about proper linguistic usage. So it would appear that if the is/ought gap is to be negotiated successfully, there must be analytic bridge principles that link moral terms and concepts with nonmoral terms and concepts. Moreover, although linking moral terms and concepts analytically with any sort of nonmoral, descriptive terms and concepts would serve to bridge the gap, most serious philosophical efforts to find any such analytic connections represent versions of ethical naturalism (see Naturalism in ethics). Ethical naturalism (at least in its traditional form) involves the attempt to define basic moral terms and concepts by terms and concepts that describe or refer to the sorts of natural properties and relations that are the subject of scientific inquiry. Thus, those who wanted to defend Hume's law were particularly concerned to refute versions of ethical naturalism.

One of the most forceful defences of Hume's law was offered by G.E. Moore (1903), who claimed that all attempts to define moral terms and concepts using naturalistic terms and concepts commit the 'naturalistic fallacy' (see Moore, G.E. §1). To expose this fallacy, Moore noted that for any genuine definition of a moral term like 'good' by some naturalistic term, N, the question, 'Entity E has property N, but is it good?', should be a closed question, that is, a question the answer to which anyone would know to be affirmative simply on the basis of understanding it. But he pointed out with a great deal of plausibility that all such questions were 'open questions', indicating that no such proposed definitions were genuine.

2 Searle's challenge

In 1964, John Searle published what became a much discussed paper, 'How to Derive "Ought" from "Is"', in which he challenges Hume's law by offering a deduction of an 'ought' statement from a set of factual statements. Here are the basic steps in his alleged deduction:

(1) Jones uttered the words, ‘I hereby promise to pay you, Smith, five dollars.’
(2) Jones promised to pay Smith five dollars.
(3) Jones placed himself under (undertook) an obligation to pay Smith five dollars.
(4) Jones is under an obligation to pay Smith five dollars.
(5) Jones ought to pay Smith five dollars.

Searle argues that philosophers have generally failed to recognize that in addition to ‘brute facts’, such as ‘John is six feet tall’, there are ‘institutional facts’, facts that presuppose certain institutions like marriage, promises and private property. These institutions are defined by systems of rules - constitutive rules - and some of these rules, like the ones characteristic of the institution of promising, involve obligations, permissions and responsibilities. Searle’s deduction, then, is supposed to work by appealing to an institutional fact (Jones made a promise), which, given the constitutive rules that define what a promise is, allows one to infer something about what Jones ought to do.

Searle’s deduction works only if he is right in claiming that the full-blown argument (including the supplementary premises) does not represent or presuppose any evaluative and specifically moral claims. Searle’s critics doubt that his deduction is successful on this count.

3 Some implications of accepting Hume’s law

But what if Hume’s law is correct? What are the implications for the logic of moral argument? Here are three observations. (1) We have noted that Hume’s law prohibits any *deduction* of moral statements from factual premises, but this leaves open the possibility that moral statements can be inferred correctly from factual premises by some *nondeductive* mode of inference, perhaps inductively. (2) Moreover, even if Hume’s law is correct, the so-called ‘autonomy of ethics’ thesis does not, strictly speaking, follow. Recall that, according to this thesis, moral discourse is autonomous in the sense that moral claims cannot be deduced from a set of nonmoral premises (see Autonomy, ethical §5). But, even granting Hume’s law, it might still be possible to derive moral conclusions from nonmoral normative (and hence nonfactual) premises. For instance, some philosophers have wanted to derive substantive moral conclusions from normative claims about rationality (where there is no attempt to construe rationality claims as a type of factual claim) (see Practical reason and ethics §3). So, the truth of Hume’s law does not establish the autonomy of ethics. (3) Even if there are no bridge principles directly linking moral concepts with nonmoral concepts by means of some analytic definition, there might still be bridge principles, expressing what some have called ‘synthetic definitions’ of moral terms, patterned after the sorts of definitions that are offered in science (see Brink 1989; Boyd 1988).

These remarks make clear that Hume’s law can be strengthened in two ways: by prohibiting inductive as well as deductive inference from the factual to the moral, and by prohibiting transition from any sort of nonmoral claims, including nonmoral normative claims, to moral claims. Presumably, many defenders of Hume’s law would also want to defend a strengthened version of the law that would prohibit the possibilities just mentioned for negotiating the is/ought gap. If these philosophers are right, where does that leave things with our main question about the logic of moral argumentation?

4 Universalizability and the role of principles

Some philosophers, who accept Hume’s law in both its original and its strengthened versions, claim that the meanings of moral terms and concepts impose special consistency constraints on proper moral argumentation. One such widely discussed consistency constraint stems from the alleged *universalizability* of moral statements (see Universalism in ethics). The basic idea is that any two or more relevantly similar objects being morally evaluated must receive the same moral evaluation. Thus, if Jane’s lying to Fred on some occasion was morally permissible, then the same moral evaluation holds for any relevantly similar action. Of course, everything depends on how ‘relevantly similar’ is interpreted.

The most influential recent treatment of universalizability is owing to R.M. Hare, as presented in *Freedom and Reason* (1963). For Hare, one situation is relevantly similar to the first if it shares with the first all of those qualitative properties, P^1-P^n, that served as the basis (namely, one’s reasons) for the original judgment. For example, if Peter judges that Paul’s action was wrong because it was a case of misleading a customer about the

quality of a product in order to make a sale, then Peter is bound, on pain of logical contradiction, to judge of any other action having these features that it too is wrong, or else withdraw his original moral judgment. One immediate implication of Hare's thesis of universalizability is that moral judgments entail universal moral principles. The moral judgment that action A is wrong because it has properties P^1-P^n commits one to the moral principle, 'Any action having properties P^1-P^n is wrong'. Thus, on Hare's view, even if there are no nonmoral bridge principles that would link moral concepts to nonmoral concepts, correct moral reasoning and argumentation about the morality of specific cases nevertheless exemplify the *subsumptive* model of reasoning: particular objects of moral evaluation are subsumed under a moral principle which governs a range of relevantly similar cases.

Hare's universalism, and in particular his use of the thesis of universalizability, is apparently open to certain counterexamples. If, for example, one judges that some particular action performed on some particular occasion was wrong because in that situation properties P^1, P^2 and P^3 were present, then even if in some new situation the same properties are present, there may be some other property which, in the new situation but not in the original situation, defeats the reasons in favour of judging the action to be wrong. Of course, the defender of universalizability will reply that the two cases are not relevantly similar because in addition to all of those features that count in favour of some particular moral evaluation, we must also recognize any features that count against that same evaluation. The second case, then, is not relevantly similar to the first one and we have no violation of the principle of universalizability. Thus, the defender of universalizability is moved to broaden the universalizability base (and hence the account of relevant similarity) to include not only those properties taken as reasons in favour of a particular moral evaluation, but also those properties taken as reasons against a particular moral evaluation. But this manoeuvre is not entirely satisfactory since, in addition to both positive and negative reasons regarding some moral evaluation of a situation, there are all sorts of potentially relevant defeaters whose absence is a condition of the correct moral evaluation about the particular case. For example, if a man stops to help a woman whose car has broken down, our reasons for moral approval include obvious facts about the situation (one person needing help, another stopping to render aid, and so on). But there are all sorts of possible defeaters whose absence is required for our positive moral evaluation of the man's actions, including, for instance, that his motive is not to seduce or in any way harm the woman. So in addition to properties that figure among a person's reasons there are other relevant aspects including the absence of certain defeaters that affect moral judgments about particular cases. And so the defender of universalizability seems forced to broaden the universalizability base even further. But once one begins to broaden the universalizability base in this way so that any aspect of a situation (including both properties instantiated in the situation and those potential defeaters that are not instantiated) counts as part of what makes two situations relevantly similar, what started out as an interesting thesis yielding interesting moral principles approaches triviality. That is, broadening the universalizability base in this way tends to reduce the thesis to the claim that any two exactly similar objects of moral evaluation must be judged in the same way. But then, the sorts of moral principles yielded by the thesis of universalizability tend to become less useful in constraining moral argumentation - they do not apply to a very interesting range of cases.

But apart from problems for Hare's notion of universalizability, there remains the idea that correct moral reasoning proceeds by way of subsumption under moral principles. As we shall see, however, the subsumption model is not without its problems. To understand the problems we need to say a bit more about moral principles.

5 Basic moral principles and the universality of reasons thesis

Many moral philosophers have supposed that underlying all right and wrong actions is some nonmoral feature or property (or perhaps small set of them) whose presence makes all right actions right and whose absence makes all wrong actions wrong. One traditional aim of moral theory has been to discover such features or properties, which can then be expressed as basic moral principles - principles that tell us what, ultimately, makes an action right or wrong. Some philosophers have been *ethical monists*: they suppose that there is some single ultimate feature whose presence makes right actions right and whose absence makes wrong actions wrong. For example, according to hedonistic versions of act utilitarianism, facts about how much pleasure and pain would be experienced by persons (and perhaps other sentient creatures) were some action to be performed determine in every case whether or not the action if morally right (see Utilitarianism; Hedonism). In contrast, *ethical pluralists*, such as W.D. Ross 1930), insist that there is no such single ultimate feature, but rather a small set of irreducible ultimate features whose presence or absence tends to make actions either right or wrong (depending on the feature in question), even though the presence or absence of any one such feature may not be decisive in determining whether or not an

action is (all things considered) right (see Moral pluralism). Despite their disagreement over the number of ultimate features, both monists and pluralists are united in accepting what can be called the *universality of reasons* thesis: there is at least one ultimate right/wrong-making feature of actions such that for it (1) it is morally relevant whenever they are present and (2) it always counts in the same way - either as a right-making feature or as a wrong-making feature. And so, for both camps, correct moral reasoning proceeds by way of subsuming particular cases calling for moral evaluation under basic moral principles.

The universality of reasons thesis is challenged by so-called moral particularists who then reject the subsumptive model of moral reasoning and argumentation.

6 Particularism, reasons holism, and the rejection of moral principles

Moral particularism rejects the universality of reasons thesis in favour of what some call *reasons holism*, according to which what counts as a reason in some particular case, and how it counts, is a matter of the details of the particular situation. Reasons holism finds intuitive support by reflecting on common examples. For instance, normally the fact that I borrowed a book from you is a reason for me to return it to you. But if I learn that you have stolen the book, then the fact that I borrowed it from you is no reason at all to return it to you; in fact it seems to be a reason against doing so.

For our purposes, the important thing to notice is that reasons holism amounts to a rejection of basic moral principles (at least a rejection of the idea that such principles are required for making sense of moral reasoning and the difference between correct and incorrect moral argumentation) since such principles, as usually interpreted, presuppose that the properties featured in them are always morally relevant and relevant in the same way. But if basic moral principles are not (or need not be) involved in correct moral argumentation, what does the particularist have to say about such argumentation? Furthermore, since in ordinary moral reasoning and argumentation we often do appeal to moral generalizations, principles or rules in defending our moral views about particular cases, how can the particularist accommodate this phenomenon?

In response to the first question, the particularist insists that correct moral reasoning and argumentation, instead of being a matter of subsuming particular cases under general principles, proceeds by examining the details of particular cases and making judgments based on one’s moral discernment about the case at hand. The particularist accepts the idea that relevantly similar cases must be judged in the same way, but insists (contra universalists) that because of the potential complexity of particular cases and the fact that what counts as a reason is a contextually sensitive matter, there are no useful moral principles that force one, on pain of logical contradiction, to come to some particular moral conclusion about the case in hand. Rather, instead of relying on moral principles to guide proper moral reasoning and argumentation, the particularist insists on the use of trained moral perception which allows one to discern the morally relevant features in a particular case and then assess their bearing on the morality of the case. In response to the second question, particularists can allow that a moral principle can serve as a useful heuristic, reminding us of the sort of importance a property can have in particular circumstances. But as mere heuristic devices, moral principles are not cast in the role of premises in moral arguments guiding us to make judgments about present cases that are consistent with past moral judgments (see Moral particularism).

The particularist mounts a fairly strong case against certain allegedly ultimate properties conforming to the universality of reasons thesis, as the borrowed book example and other such examples make clear. However, it is harder to imagine cases in which the fact that someone’s action would be a case of knowingly causing the death of a normal human being is not morally relevant or indeed counts in favour of performing the act. The same can be said for actions in which one knowingly causes others to experience significant pain. If this speculation is correct, then perhaps universalism can survive the objections of the particularist.

The ethical naturalists and some anti-naturalists like Hare agree that correct moral reasoning and argumentation is subject to constraints of logical consistency imposed on such reasoning and argumentation by universal moral principles. Thus, both subscribe to a subsumptive model of moral reasoning and argumentation, according to which proper judgments about particular cases are subsumed under universal moral principles. The main difference between Hare and the naturalists is over the status of such principles. In sharp contrast to the universalists, the particularists reject the universalist assumption about moral reasons and consequently reject the subsumptive model of moral reasoning and argumentation. Instead, the particularist argues that correct moral reasoning and

argumentation can rely on trained moral perception of the morally relevant details of particular cases as a way of coming to have correct or at least justified moral beliefs about particular cases.

Logic, ancient

Western antiquity produced two great bodies of logical theory - those of Aristotle and the Stoics. Both aim to explain what distinguishes good arguments from bad. Both see that the best arguments are valid and that an argument's validity depends on its form. For both, therefore, logic's business is to identify the valid argument forms. Both theories do this by laying down a small number of basic argument forms - Aristotle's 'perfect syllogisms', the Stoics' 'indemonstrables' - and rigorously deriving other valid forms from them. Both theories also try - though in a less systematic manner - to classify the ways in which an argument can go wrong.

Here the similarities between these two logics end. Their most significant differences can be illustrated by comparing basic argument forms from each. The argument 'Every swan is an animal and every animal is moving, so every swan is moving' has the same form as the argument 'Every musician is human and every human is a substance, so every musician is a substance'. The Aristotelian expression of this form is 'A belongs to all B and B belongs to all C, so A belongs to all C'. In this form the letters 'A', 'B' and 'C' stand for any terms whatever, and 'A belongs to all B' replaces 'Every B is an A'. This represents the Aristotelian approach. Compare it with the following. The argument 'If it is day then it is light, it is day, so it is light' has the same form as the argument 'If Dion walks then Dion moves, Dion walks, so Dion moves'. This form is expressed by the Stoics as 'If the first then the second, the first, so the second'. Here the expressions 'the first' and 'the second' stand for any declarative sentences whatever.

In both cases, the validity of the argument form is tantamount to the validity of all arguments having that form (though the Stoics, unlike Aristotle, require that the precise words used in an argument should recur in its form). But the Aristotelian argument form is different in kind from the Stoic one: while it abstracts from terms, the Stoic form abstracts from sentences. Aristotelian logic is a term logic, Stoic logic a sentential one.

1 Aristotle's logic: general

Aristotle was the first great logician (see Aristotle §§4-5, 7). His logical writings are traditionally grouped together as the Organon, comprising *Categories*, *De interpretatione*, *Prior Analytics*, *Posterior Analytics*, *Topics* and *On Sophistical Refutations*.

Categories and *Topics* share a concern with distinguishing different types of predication. In *Categories* beings are classified into substances, quantities, qualities, relatives, places, times, positions, states, actions and affections. Within any one category, beings are related to one another in tree-structures linked by the 'said of' relation; for example, in the category of substance, animal is said of swan and of horse. Between categories there are relations of 'inherence': for example, colour (a quality) inheres in body (a substance). The 'said of' and inherence relations underlie all true predications. Substances are either 'primary' (for example, this horse) or 'secondary' (for example, horse). Among all beings, primary substances are basic: all others are said of or inhere in primary substances, whereas primary substances neither are said of nor inhere in anything. Though *Categories* is concerned mainly with ontological questions, it also states a few principles of inference, including the following: 'When one thing is predicated of another as subject, everything said of the predicate will also be predicated of the subject'.

Topics divides predications into four types: (1) essential and convertible, (2) essential and non-convertible, (3) non-essential and convertible, (4) non-essential and non-convertible. Any predicate thus stands to its subject as (1) a definition (for example, 'biped land-animal' is the definition of man), (2) a 'genus' or 'differentia' (for example, colour is the genus of white, biped is the differentia of man among land-animals), (3) a 'peculiarity' (for example, 'walking in the gymnasium' would be a peculiarity of a particular man if he were the sole walker there) or (4) an 'accident' (for example, evil is an accident of chance). These four types of predication are traditionally known as the 'predicables', and *Topics* formulates a large number of principles (or, commonplaces, 'topoi') concerning them, for example, 'the genus is predicated essentially of whatever the species is predicated of' (IV 2).

The ninth book of *Topics* is known by the separate title *On Sophistical Refutations*. Aristotle there distinguishes fallacies that depend on linguistic factors (such as lexical or syntactic ambiguity) from those that do not.

Fallacies not depending on linguistic factors are seven. The fallacy of 'accident' attributes to a thing what belongs only to an accident of the thing, for example, supposing Coriscus happens to be approaching, it would be wrong to

infer that you do not know Coriscus, given the premise that you do not know who is approaching. The fallacy of '*secundum quid*' argues from a qualified to an unqualified statement, for example, supposing you have a belief about a non-being, it would be wrong to infer that a non-being *is*, given the premise that a non-being is-an-object-of-belief. The fallacy of '*ignoratio elenchi*' argues to the wrong point, for example, by showing that something is double in height when required to show that it is double in width. The fallacy of '*petitio principii*' or begging the question is committed when someone 'tries to prove by means of itself what is not known by means of itself' (*Prior Analytics* II 16). The fallacy of 'affirming the consequent' is committed when the direction of implication is confused, for example, by confusing the statement that whatever is created has a beginning with the statement that whatever has a beginning is created. The fallacy of 'false cause' arises from the inclusion of redundant material in a *reductio* argument, for example, arguing that the diagonal is incommensurable with the side of a square because if it were commensurable, *and if traversing a distance entailed first traversing half the distance*, then we would be committed to the absurd statement that motion is impossible. The fallacy of 'many questions' occurs when what in fact are several questions are treated as if they were just one. (See Fallacies.)

De interpretatione contains a semantic theory of categorical statement-forms. *Prior Analytics* contains the theory of the syllogism. *Posterior Analytics* applies the syllogistic to the special case where a syllogism embodies scientific knowledge. It deals with the orderly exposition of a body of scientific knowledge in an axiomatic deductive system: the axioms of such a system will state how things are in themselves and necessarily, and the deductions' premises will explain the truth of their conclusions.

2 Aristotle's semantics

Non-modal propositions are of four forms: '*A* belongs to all *B*', '*A* belongs to no *B*' (these two are 'universal'), '*A* belongs to some *B*' and '*A* does not belong to some *B*' (these two are 'particular'). The letters '*A*' and '*B*' stand for terms, that is, nouns or noun phrases. '*A*' is predicate and '*B*' subject in these forms. The first and third forms are 'affirmative', the second and fourth 'negative' (*Prior Analytics* I 2).

Semantics for universal propositions are given in the so-called '*dictum de omni et nullo*': 'We use the expression ''predicated of all'' when none of the subject can be taken of which the other term cannot be said, and we use ''predicated of none'' likewise' (I 1).

The universal affirmative and particular negative form a pair of 'contradictories', as do the universal negative and particular affirmative. The universal affirmative and universal negative are 'contraries'. Contradictories cannot both be true, nor can they both be false; contraries cannot both be true but may both be false (*De interpretatione* 7).

'*A* belongs to no (or some) *B*' implies - Aristotle says 'converts to' - '*B* belongs to no (or some) *A*'. '*A* belongs to all *B*' converts to '*B* belongs to some *A*' (*Prior Analytics* I 2). This can be so only if the universal affirmative has 'existential import', that is, implies that something is *A* and something is *B*.

Modal propositions are of the forms '*A* belongs necessarily (or contingently) to every *B*', '*A* belongs necessarily (or contingently) to no *B*', '*A* belongs necessarily (or contingently) to some *B*' and '*A* does not belong necessarily (or contingently) to some *B*'. Aristotle does not state truth-conditions for modal propositions, but he does define the 'contingent' (*endechomenon*) as 'that which is not necessary but, being assumed, results in nothing impossible'. He also distinguishes two senses in which *A* might be said to belong contingently to all *B*: either *A* is contingent for everything to which *B* belongs or *A* is contingent for everything for which *B* is contingent (I 13).

'*A* belongs necessarily to no (or some) *B*' converts to '*B* belongs necessarily to no (or some) *A*'. '*A* belongs contingently to some *B*' converts to '*B* belongs contingently to some *A*'; but '*A* belongs contingently to no *B*' does not convert (I 3). Contingency modals are subject to the following distinctive laws: '*A* belongs contingently to all *B*' is equivalent to '*A* belongs contingently to no *B*', and analogously for particulars (I 13).

3 Aristotle's syllogistic

Aristotle defines a 'syllogism' as 'discourse in which, certain things being proposed, something other than them results of necessity from their being so' (I 1). Syllogisms have at least two premises. In a two-premised syllogism, one term (the 'middle') occurs in both premises. Any two-premised syllogism is in one of three 'figures'

depending on whether the middle term is (1) once predicate and once subject or (2) twice predicate or (3) twice subject. The conclusion's predicate is the 'major' term, and its subject the 'minor'. The premises are designated as major or minor depending on which of the conclusion's terms occurs in them.

The non-modal syllogistic is based on four 'perfect' or complete syllogisms in the first figure. These (with their medieval names) are 'Barbara' (*A* belongs to all *B* and *B* to all *C*, so *A* belongs to all *C*), 'Celarent' (*A* belongs to no *B* and *B* to all *C*, so *A* belongs to no *C*), 'Darii' (*A* belongs to all *B* and *B* to some *C*, so *A* belongs to some *C*) and 'Ferio' (*A* belongs to no *B* and *B* to some *C*, so *A* does not belong to some *C*).

Modal syllogisms may be pure (with premises and conclusion all containing the same modality) or mixed. Pure modal syllogisms all derive from pure perfect first-figure syllogisms containing either the mode of necessity or that of contingency throughout. Mixed modal syllogisms all derive from mixed perfect first-figure syllogisms whose major premise and conclusion both contain the mode of necessity (or that of contingency), but whose minor premise is non-modal. Thus, Aristotle counts as perfect, not only the four non-modal syllogisms of figure one, but four pure necessity-syllogisms, four pure contingency-syllogisms, four mixed necessity-syllogisms and four mixed contingency-syllogisms - a total of twenty. Not perfect (or even valid) are those first-figure inferences in which the major premise is non-modal while the minor premise and conclusion contain an identical modality.

The perfect syllogisms function as axioms from which other syllogisms are derived (Aristotle says other syllogisms are 'reduced' to the perfect ones). Aristotle's syllogistic is thus the first axiomatized system in history (predating Euclid).

An incomplete syllogism may be perfected in one of three ways. First, by 'direct reduction':

> In the second figure, if the negative proposition is necessary, then the conclusion will be necessary.… Let *A* be possible for no *B*, and simply belong to all *C*. Then, since the negative converts, *B* is possible for no *A*. But *A* belongs to all *C*; so *B* is not possible for any *C*.
>
> (I 10)

Here the first premise is converted, thus producing a pair of premises from which the desired conclusion follows by virtue of a 'Celarent' with necessary major and non-modal minor. Second, by 'indirect reduction':

> If *A* belongs to all *C* and *B* does not belong to some *C*, it is necessary that *B* does not belong to some *A*. For if *B* belongs to all *A* and *A* to all *C*, *B* belongs to all *C*; but we supposed it did not belong.
>
> (I 6)

Here, by taking the conclusion's contradictory together with the first premise, we get the second premise's contradictory by virtue of 'Barbara'. Third, by 'ecthesis':

> when both *A* and *B* belong to all *C*, *A* will belong necessarily to some *B*.… If *A* and *B* both belong to all *C*, and we take one of the *C*s, say *D*, *A* and *B* will belong to this, so *A* belongs to some *B*.
>
> (I 6)

Here the inference's validity is explained by reference to an individual, *D*, which is supposed to be both an *A* and a *B*: there must be such an individual if *A* and *B* both belong to all *C*, but if there is such an individual then *A* belongs to some *B*.

In Book II Aristotle works out some metatheorems for his syllogistic, including the following:

(1) A syllogism with true premises must have a true conclusion.
(2) Any most general form of syllogism may have (a) all premises true, (b) some premises true and some false, (c) all premises false and the conclusion true.
(3) The falsity of all (or some) of the premises of a syllogism stated in its most general form does not necessitate the truth of the conclusion.
(4) No syllogism stated in its most general form commits a logical *petitio principii*, that is, none has the form '*p*, *q* so *r*' where *p* implies *r*. This result does not hold for all syllogistic forms: '*A* belongs to all *B*, *B* belongs to all *B*, so *A* belongs to all *B*' commits a logical *petitio*.
(5) No syllogism by virtue of its most general form commits an epistemological *petitio* in the sense that knowing

or believing premises of that form implies knowing or believing the corresponding conclusion.

4 Theophrastus

Aristotle's successor Theophrastus also wrote on logic. None of his logical writings survives, but we have reports in ancient sources, notably Alexander of Aphrodisias' commentary on Aristotle's *Prior Analytics*. Theophrastus further developed his master's syllogistic in five main ways. First, he pointed out that first-figure syllogisms may have indirect conclusions, for example, from the premises '*A* belongs to all *B* and *B* to all *C*' we can deduce '*C* belongs to some *A*'.

Second, in modal semantics Theophrastus rejected Aristotle's definition of the contingent as two-way possibility, and consequently rejected the equivalence between '*A* contingently belongs to all *B*' and '*A* contingently belongs to no *B*'. He also took '*A* contingently belongs to no *B*' to convert to '*B* contingently belongs to no *A*'.

Third, he considered Aristotle's perfect mixed necessity-syllogisms invalid, requiring instead that the modality of the conclusion be no stronger than the weakest modality in the premises.

Fourth, with regard to 'prosleptic' propositions such as '*A* belongs to all of that to none of which *B* belongs' (briefly discussed by Aristotle), Theophrastus considered them to be equivalent to ordinary categoricals.

Fifth, Theophrastus recognized 'wholly hypothetical' syllogisms such as 'If *A* then *B*, if *B* then *C*, so if *A* then *C*', and arranged them in three figures according to the position of their 'middle'. The letters '*A*', '*B*' and '*C*' here stand for sentences rather than terms.

5 Stoic logic and semantics

Among the Stoics and their predecessors, the most famous logicians were Diodorus Cronus, Philo (the Dialectician) and Chrysippus. We have only a few fragments of their work, plus reports in Sextus Empiricus' *Outlines of Pyrrhonism* and *Against the Logicians*, Diogenes Laertius' *Lives of the Philosophers* and other ancient sources.

The Stoics distinguished four causes of argumentative failure: 'incoherence', as in the argument 'If it is day it is light, wheat is being sold in the market, so Dion is walking'; 'redundancy', as in the argument 'If it is day it is light, it is day, Dion is walking, so it is light'; 'formal invalidity', as in 'If it is day it is light, it is not day, so it is not light'; and 'deficiency', as in 'Either wealth is good or bad, it is not good, so it is bad', which is said to be deficient because the first premise omits mention of the possibility that wealth is neither good nor bad. In the first three cases (but not the fourth) the argument as a whole does not instantiate a valid form, though only the first and third are cases of invalidity.

They also studied paradoxes, including the liar paradox ('If you say that you are lying, and speak the truth, then you are lying'), 'the hooded man' (which, like Aristotle's fallacy of accident, concerns an unrecognized friend concealed beneath a hood), the 'sorites' or heap (which asks how many grains it takes to make a heap; see Vagueness §2) and 'the horned man' ('What you haven't lost you still have, you haven't lost horns, so you still have horns' - a relative of Aristotle's fallacy of many questions).

Stoic semantics and syllogistic is a propositional logic, dealing with the ways in which one proposition may be formed from one or more propositional components. The forms of propositional composition on which the Stoics concentrated are negation, conjunction, disjunction and the conditional. They recognized that a conjunction 'the first *and* the second' is true if and only if both conjuncts are true. A disjunction 'either the first *or* the second' they took in the exclusive sense, requiring that one and only one disjunct be true.

The semantics of conditionals was hotly debated by the Stoics and other contemporary logicians. According to Philo, a conditional proposition ('If the first then the second') is true if and only if it does not have a true antecedent and a false consequent. According to Diodorus Cronus, a conditional is true if and only if it neither is nor ever was possible for the antecedent to be true and the consequent false. A third semantics for conditionals - 'by connection' - proposed that the antecedent be 'incompatible' with the denial of the consequent. A fourth - 'by suggestion' - proposed, somewhat vaguely, that the consequent be 'potentially in' the antecedent. (See Philo the Dialectician §2; Diodorus Cronus §§3-4; Consequence, conceptions of §2.)

6 Stoic syllogistic

There are five 'indemonstrables':

(1) If the first then the second, the first, so the second.
(2) If the first then the second, not the second, so not the first.
(3) Not both the first and the second, the first, so not the second.
(4) Either the first or the second, the first, so not the second.
(5) Either the first or the second, but not the second, so the first.

Further inferences were shown valid by the application of one or more rules to the indemonstrables. There were four of these rules, of which only two are now known. The first is equivalent to Aristotle's rule of indirect reduction: if two propositions imply a third, then either of these together with the negation of the third implies the negation of the remaining one. The third rule is the one which underlies Aristotle's procedure of direct reduction: if two propositions imply a third then the first, together with any propositions that imply the second, implies the third.

The third rule is used in proving the inference 'If the first and the second then the third, not the third, but the first, so not the second'. By the second indemonstrable we have 'If the first and the second then the third, not the third, so not both the first and the second'. Applying the third rule to this and the third indemonstrable we get 'If the first and the second then the third, not the third, but the first, so not the second'.

Both the first and third rules are used in the following (modern) proof of the validity of the Stoic inference 'If you know you are dead then you are not dead, if you know you are dead then you are dead, so you do not know you are dead', whose form is 'If the first then not the second, if the first then the second, so not the first'. Applying the first rule to the first indemonstrable we get (a) 'Not the second, the first, so not if the first then the second'. But, again by the first indemonstrable, we have (b) 'If the first then not the second, the first, so not the second'. Applying the third rule to (a) and (b) we get (c) 'If the first then not the second, the first, so not if the first then the second'. And applying the first rule to (c) we get 'If the first then not the second, if the first then the second, so not the first'.

The Stoics accepted the inference 'If the first then if the first then the second, but the first, so the second'. This is said to be validated by two applications of the first indemonstrable. But strictly speaking - and the Stoics were fond of speaking strictly - all that is validated by that procedure is the inference 'If the first then if the first then the second, but the first, *and the first*, so the second'. What is needed to validate the target inference is a 'rule of contraction': if an inference with a repeated premise is valid then so is the same inference without the repetition. This rule is also tacitly used in the above proof of the 'knowing you are dead' syllogism. The rule of contraction, though required by the Stoic system, is nowhere stated in the surviving sources.

The Stoics recognized that if an argument is valid then the conditional whose antecedent is the conjunction of the argument's premises and whose consequent is its conclusion is necessary. Thus, the validity of the first indemonstrable implies the necessity of the conditional 'If ''the first and if the first then the second'' then the second'.

Some parts of Aristotelian metatheory - namely metatheorems (2c), (3) and (5) in §3 above - do not carry over to the system of indemonstrables. (2c) Given Philonian semantics for the conditional, not both premises of the first indemonstrable can be false: if 'the first' is false then 'If the first then the second' is true. (3) Consequently, given Philonian semantics for the conditional, if both premises of the first indemonstrable are false, the conclusion must be true. (5) The first indemonstrable is epistemically question-begging on the Philonian reading of the conditional: the premise 'If the first then the second' on this reading could be known only if 'the first' were known to be false (which it could not seeing it is known to be true) or 'the second' were known to be true. (But none of this is the case for non-Philonian readings.)

7 Modern interpretations

The 'traditional' logic books of the nineteenth and early twentieth centuries reduced categorical and hypothetical syllogistic to rules of thumb and deprived it of its systematicity and rigour. The categorical syllogism was treated

as an inference, exemplified by ‘All men are mortal, Socrates is a man, so Socrates is mortal’, an example nowhere to be found in *Prior Analytics*. The modal syllogism, if mentioned at all, was dismissed as useless or incoherent.

Łukasiewicz (1951) was the first to interpret Aristotle’s syllogistic as a formalized axiomatic system, rigorous by the highest standards. He returned to Aristotle’s text, and interpreted the syllogism not as an inference but as a conditional statement whose antecedent conjoins two universal or particular (not singular) statements. He was thereby able to treat the syllogistic as an axiomatic system whose theses have the structure of conditional statements with conjunctive antecedents. Because of this structure, the system required an ‘auxiliary theory’ of propositional logic, specifying the logic of conditionals, conjunctions and negation. Practically none of this auxiliary theory is to be found in Aristotle. From Łukasiewicz’s point of view the Stoics therefore marked an advance on Aristotle in articulating a propositional logic.

Corcoran (1972) rejected Łukasiewicz’s interpretation of Aristotelian syllogistic as an axiomatic system whose theses are conditional statement-forms; instead he treated it as a natural-deduction system, thus avoiding the need for an auxiliary propositional logic. An Aristotelian syllogism is for him not just a set of premises and a conclusion but something with a deductive structure. This interpretation enabled him to give modern formal representations not only of Aristotle’s syllogisms but also of Aristotle’s own manner of proving them. He could view Aristotle’s system ‘from the standpoint of modern logic’ without imputing gross oversights to him.

Smiley’s independent work arrived at these same results, but went further than Corcoran in abandoning the aim that every expressible, semantically valid formula should be a thesis of the system. He did this on two grounds. First, Aristotelian syllogistic is not governed by the ‘rule of expansion’ (if certain premises imply a conclusion then any set that includes those premises implies the conclusion). Second, it does not obey the rule of contraction (see §6). The addition of either of these rules to Aristotle’s system, Smiley showed (1973), leads to un-Aristotelian results. The rule of expansion entails that from two mutually contradictory premises every conclusion follows. Thus ‘*A* belongs to every *B*, *A* does not belong to every *B*, so *C* belongs to some *D*’ should be a syllogism; but it is not. Since ‘*A* belongs to all *C*, *A* belongs to all *C*, so *A* belongs to some *A*’ is a syllogism, contraction would entitle us to drop the repetition and say that ‘*A* belongs to all *C*’ implies ‘*A* belongs to some *A*’. So ‘*A* belongs to no *A*’ would imply ‘*A* does not belong to all *C*’. Therefore the premises ‘*B* belongs to no *A*, *B* belongs to all *A*’ - which imply ‘*A* belongs to no *A*’ - would also imply ‘*A* does not belong to all *C*’. However, ‘*B* belongs to no *A*, *B* belongs to all *A*, so *A* does not belong to all *C*’ is not an Aristotelian syllogism. On Smiley’s interpretation, a syllogism is a deduction in a sense of ‘deduction’ that requires all premises to be used, and which heeds the number of times a premise is used. Smiley constructed a formal system based on such a notion of deduction, proved its completeness, and constructed a decision-procedure for it. These results allowed him to formalize some of Aristotle’s own metatheory, in particular metatheorem (3) (see §3 above).

Thom (1981, 1996) further developed the Smiley interpretation, showing that Aristotle’s syllogistic does not include proper substitutions in theses: thus, while ‘*A* belongs to all *B*, *B* belongs to all *C*, so *A* belongs to all *C*’ is Aristotelian, ‘*A* belongs to all *B*, *B* belongs to all *A*, so *A* belongs to *A*’ is not. This restriction is needed if the interpreter is to construct a formalization to which all of Aristotle’s metatheory applies, since some of that metatheory holds only for theses stated in their most general form (see (2)-(5) in §3 above). He also showed how to develop Aristotle’s sketchy remarks about ‘ecthesis’ into a natural deduction system of singular syllogisms, on which the whole syllogistic (modal as well as non-modal) can be based.

Modern interpretations of modal syllogistic take their impetus from McCall (1963), who restored faith in the rigour of Aristotle’s modal system by formalizing it axiomatically. Johnson (1989) provided a formal semantics for McCall’s formalization. Johnson’s semantics treats ‘*A* belongs necessarily to every (or no) *B*’ as true if and only if the *B*s are among (or exclude) the *essential A*s; ‘*A* belongs necessarily to some *B* (or necessarily does not belong to some *B*)’ he treats as true if and only if some essential *B* is an essential *A* (or is an essential non-*A*). If, as Johnson required, the truth-conditions of Aristotle’s modal sentences make reference to the essential *A*s, then it seems that modal syllogistic is underpinned by some doctrine of essentialism. This idea was developed by Patterson (1995), who explored philosophical links between the semantics of modal sentences and the doctrine of the predicables.

Modern interpretations of Stoic logic spring from the work of Mates (1953), and Kneale and Kneale (1962). The complex relationship between the Stoic and Aristotelian systems has been studied by Frede (1987).

Logic, medieval

Medieval logic is crucial to the understanding of medieval philosophy, for every educated person was trained in logic, as well as in grammar, and these disciplines provided techniques of analysis and a technical vocabulary that permeate philosophical, scientific and theological writing. At the practical level, logic provided the training necessary for participation in the disputations that were a central feature of medieval instruction, and whose structure - with arguments for and against a thesis, followed by a resolution - is reflected in many written works. At the theoretical level, logic, like other subjects, involved the study of written texts through lectures and written commentaries. The core of the logic curriculum from the twelfth century onwards was provided by the logical works of Aristotle. These provided the material for the study of types of predication, the analysis of simple propositions and their relations of inference and equivalence, the analysis of modal propositions, categorical and modal syllogisms, fallacies, dialectical Topics, and scientific reasoning as captured in the demonstrative syllogism. Comprehensive as this list might seem, medieval logicians realized that other logical subjects needed to be investigated, and, again from the twelfth century onward, new techniques and new genres of writing appeared. The main new technique involved the use of 'sophismata', or puzzling cases intended to draw attention to weaknesses and difficulties in logical definitions and rules. The new genres of writing especially included works on 'supposition theory', which concerned the types of reference that the subjects and predicates of propositions have in different contexts, and works on 'syncategoremata', which concerned the effect on sense and reference produced by the presence and placing of such logical terms as 'all', 'some', 'not', 'if...then', 'except', and so on. Other important topics for investigation include 'insolubles', or semantic paradoxes, and 'consequences', or valid inference forms. These new developments were seen as providing a supplement to Aristotelian logic, rather than an alternative. The only context in which people occasionally suggested that Aristotelian logic was inapplicable was that of Trinitarian theology, and the only logician who deliberately set out to reform logic as a whole was Ramon Llull.

The study of medieval logic involves two kinds of difficulty. In the first place, few texts are available in translation, and indeed, many are not even available in printed form. In the second place, there is a problem of interpretation. For a very long time, the specifically medieval contributions to logic were ignored or despised, and when people began to take them more seriously, there was a strong tendency to look at them through the spectacles of modern formal logic. More recently, scholars have come to realize that medieval interests cannot be mapped precisely onto modern interests, and that any attempt, for example, to make a sharp distinction between propositional and quantificational logic is misleading. The first task of the modern reader is to try to understand what the medieval logician was really concerned with.

1 Background

The story of medieval logic is the story of logic in western Europe after the split of the Roman Empire into the Latin-speaking, Catholic west and the Greek-speaking, Orthodox east (see Byzantine philosophy §3). Because this split was followed by barbarian invasions and constant upheaval, very little happened between 550 and 1000, and learning was mainly kept alive in Benedictine monasteries. However, it is important to consider the Latin texts that were transmitted, for they formed part of the basis for later developments. One very important early source is the *Peri Hermeneias* by Apuleius of Madaura which dates from the second century AD. It discusses the proposition and the categorical syllogism, and it was influential until the late twelfth century. It was the main source for Martianus Capella (early fifth century), author of *De nuptiis Philologiae et Mercurii (The Marriage of Philology and Mercury)*, Cassiodorus (sixth century), author of *Institutiones*, and Isidore of Seville (seventh century), author of *Etymologies*, all of whose encyclopedic works include sections on logic (see Encyclopedists, medieval §§4, 6, 7). Other early works include Marius Victorinus on definitions and a work attributed to Augustine, the *Categoriae decem (The Ten Categories)*, which is from the fourth-century circle of Themistius and was the most intensely studied logical work in the ninth and tenth centuries.

Most important of all are the works of Boethius. He seems to have been responsible for translating all of Aristotle's Organon (that is, his six works on logic) into Latin, and all but the *Posterior Analytics* survive. He also translated Porphyry's *Isagōgē (Introduction)*, and wrote commentaries on some of Aristotle's logic, on Porphyry and on the *Topics* of Cicero. In addition he composed monographs of his own on Division, on Topics, on

categorical syllogisms and on hypothetical syllogisms, that is, on conditional propositions and arguments built up from them (see Boethius, A.M.S. §§2-3). At first, little attention was paid to this body of writing, but signs of revival first appear at Charlemagne's court, for which Alcuin (d.804) wrote a little work on dialectic (see Carolingian renaissance §2). The first outstanding figure is Gerbert of Aurillac, who taught in the cathedral school at Reims from about 972 before becoming a bishop and finally Pope. He taught the *Logica vetus (Old Logic)* (that is, Porphyry's *Isagōgē*, Aristotle's *Categories* and *On Interpretation*), Cicero's *Topics* and a good deal of Boethius.

As western Europe became more settled, so educational institutions began to flourish. Better monastic schools (for example, Bec, where Anselm taught) and cathedral schools (see Chartres, School of) developed, and in the twelfth century, especially in Paris, schools grew up around individual masters such as Abelard and Adam of Balsham [Parvipontanus]. The monographs and commentaries of Boethius had been largely recovered by the beginning of the eleventh century and, with the *Logica vetus*, became the focus of attention. The *Liber sex principiorum (Book of Six Principles)* (that is, the last six categories, about which Aristotle had had less to say), attributed to Gilbert of Poitiers, became part of the *Logica vetus*. At the same time the philosophical study of grammar became important, with a focus on the *Institutiones grammaticae (Institutions of Grammar)* of Priscian (see Language, medieval theories of §1). Anselm's important discussion of the reference of the word '*grammaticus*' ('expert in grammar' or 'literate') shows an attempt to harmonize Aristotle's and Priscian's doctrines (see Anselm §5). By far the most outstanding figure, and the first really original logician, was Peter Abelard (§§2, 4). Unfortunately, his own turbulent life and the important events of the later twelfth century combined to diminish any influence his logical work may have had.

2 After 1150: a general survey

Logic after 1150 is shaped by four interrelated developments: the recovery of the rest of Aristotle's logical works, along with other texts; the foundation of universities and the *studia* of the new religious orders; the development of 'sophismata', a new technique for handling logical problems; and the development of new areas of logic.

New translations. Aristotle's *Topics* and *Sophistical Refutations* were known by the 1130s and the entire *Logica nova*, including the *Prior* and *Posterior Analytics*, was known by 1159 when John of Salisbury referred to them in his *Metalogicon*. All circulated in translations by Boethius, with the exception of the *Posterior Analytics*, which was translated by James of Venice in the twelfth century. Both the *Topics* (see Alexander Neckham) and the *Sophistical Refutations* were used in the twelfth century, but most especially the latter, and the *Prior Analytics* gradually displaced Boethius' works on the categorical syllogism. The *Posterior Analytics* was absorbed more slowly. The first known complete commentary is that by Grosseteste (§1), dating from the early 1220s.

In the second half of the twelfth century Arabic logic began to appear. The first part of Avicenna's *Logic* (see Ibn Sina §1), dealing with the *Isagōgē*, was translated by Gundissalinus, as was Farabi's *Catalogue of Sciences*, whose second chapter dealt with logic. The *Logic* of Ghazali was also translated. In the 1230s the logic commentaries of Averroes on the *Categories*, *On Interpretation* and the *Prior* and *Posterior Analytics* were translated, though they were less successful than the Arab works translated earlier. Some Greek commentators were also translated. Themistius' *Paraphrase of the Posterior Analytics* and some extracts from Philoponus on the *Posterior Analytics* became known in the late twelfth century. Much later William of Moerbeke translated Simplicius on the *Categories* (1266) and Ammonius on *On Interpretation* (1268). The frequently cited but now lost commentary by 'Alexander' on *Sophistical Refutations* was probably the translation of a work by Michael of Ephesus (*c*.1130). Other Greek works on logic were not translated until the Renaissance. The important thing about all these texts is not just their content but the fact that they provide a full curriculum for an organized institution. (See Aristotelianism, medieval §3 for the twelfth-century reception of translations.)

New institutions. By the beginning of the thirteenth century the Universities of Oxford, Paris and Bologna were taking shape as organized institutions. Gradually other universities were founded, along with the *studia* of the new teaching orders, especially the Dominicans (at whose Cologne *studium* Albert the Great taught) and the Franciscans (at whose London *studium* Ockham taught), and all these institutions offered a training in the liberal arts (see Encyclopedists, medieval §1). Two things should be noted. First, a degree from the arts faculty was required for all advanced (graduate) study in theology, medicine and law (though especially in Italy, medicine and law, unlike theology, could be pursued at the undergraduate level). Second, logic formed a very large part of the

arts curriculum, especially during the first two years. One reason for its importance was the large place given to disputation at all levels of university teaching: logic clearly offers training in the techniques of debate, and inculcates quickness in analysing and responding to arguments. However, university teaching also involved the close study of texts, especially the texts of Aristotle, and many commentaries, as well as original textbooks, were written by medieval logicians. (See Natural philosophy, medieval §5 for teaching practices.)

Sophismata: a new technique. Medieval logic is characterized by a new technique, the analysis and solution of sophismata. The word 'sophisma' covers two phenomena. First, there is the sophisma sentence itself, which is a logical puzzle intended to introduce or illustrate a difficulty, a concept, or a general problem. The origin of these sentences seems to lie in the twelfth-century use of '*instantiae*', or counter-examples. Second, there is the technique of the sophismatic disputation, which is used to show that the very same reasoning which supported a plausible thesis could also be used to establish something implausible. By the end of the twelfth century the sophisma was established in different genres of logical and grammatical writing. These genres included treatises on syncategoremata, that is, those words which perform a function in a sentence by negating, conjoining, disjoining and so on (see §8), and treatises on sophismata themselves. The relationship between these treatises was very close. Typically, a treatise on syncategoremata would start with a syncategorematic term and then appeal to sophismata to illustrate the difficulties its use might cause. A treatise on sophismata would start with a sophisma and, using disputational techniques, appeal to facts about a syncategorematic term or to logical distinctions to solve it, or to show that different truth-values were possible according to different senses of the sophisma sentence. Various types of sophismata and treatises on sophismata survive. It seems that in Paris the sophisma was an element of teaching, and had to be debated in the schools, that is, within a fairly formal setting. Very elaborate sophismata survive from the latter part of the thirteenth century which were given solutions by the teaching masters, for example, Boethius of Dacia, and which were often used as a vehicle for the straightforward discussion of interesting logical problems. On the face of it, Oxford sophismata seem to have been quite different. They were the subject of live debate, but this debate was at a strictly undergraduate level, and was part of the practical training in logical disputation. They were not primarily a vehicle for discussing doctrine, and they seem to disappear as a genre when the curriculum changes. Fourteenth-century Oxford sophismata had two special features. First, they exhibit a new emphasis on the '*casus*', or initial hypothesis about the context of the sophisma-sentence, which might itself be identified as the source of the problems in determining the truth-value of that sentence. This notion of *casus* played a key role in treatises on insolubles (see §10) and obligations (see §11), which are both closely linked to sophismata. Second, many of them are about natural philosophy, and introduce mathematical considerations and calculatory techniques (see Oxford Calculators §§2, 4).

Among the surviving fourteenth-century treatises on sophismata are important works by Richard Kilvington, William Heytesbury, John Buridan and Albert of Saxony. In the fifteenth century, Paul of Venice wrote on sophismata, as well as using them extensively in other works. Both the technique and the genre of writing disappeared early in the sixteenth century.

3 After 1150: new logical writings

While the writings of Aristotle were central to the logic curriculum, there were matters that he did not discuss, which left room for a considerable number of new developments. The most prominent is the so-called '*logica moderna*' or '*modernorum*' (a label coined by twentieth-century authors). Also known as 'terminist logic', this includes supposition theory and its ramifications (see §7). Treatises on supposition theory deal with the reference of subject and predicate terms in propositions, and they have as a corollary the treatises on syncategoremata, which deal with all the other terms in propositions. The material dealt with in treatises on syncategoremata was also dealt with in treatises on sophismata (see §2 above), but in the fourteenth century much of it also appeared in treatises on the 'proofs of terms' (see §8). Three more important developments are found in treatises on consequences (see §9), insolubles (see §10) and obligations (see §11).

While supposition theory constitutes the most important new development, it was not always privileged. Paris in the second half of the thirteenth century, and Bologna and Erfurt at the beginning of the fourteenth century, were centres of 'modist logic', and tended not to use supposition theory. Modist logicians (for example, Peter of Auvergne) were more interested in the sense than the reference of terms, and they made much use of the relationships between the *modi essendi* (modes of being) of things, the *modi intelligendi* (modes of understanding)

and the *modi significandi* (modes of signifying) of words. They were also characterized by their lengthy discussions of the rational nature of logic and its relation to second intentions (see §4). Another rival to supposition theory as a tool of analysis was provided by 'proofs of terms', which were particularly important in the later fourteenth century.

Another new form of writing was the comprehensive textbook. At least six survive from the thirteenth century, including those by William of Sherwood, Peter of Spain and Roger Bacon. In the fourteenth century we find those by William Ockham, John Buridan and Albert of Saxony. Some universities, especially Oxford and Cambridge, preferred to use loose collections of brief treatises on various topics, and a good example of such a collection is the *Logica parva* of Paul of Venice.

There are three things to note about these new writings. First, they were not officially part of the curriculum at most universities, but that did not prevent their being used. Second, because Latin was the common language of instruction in western Europe, a text written in one place could be used anywhere else. Peter of Spain's text was generally the most popular, but Buridan was particularly important in Poland, and in late fourteenth- and fifteenth-century Italy short texts from England were heavily used. Third, there is no genuine division between the authors of Aristotle commentaries and the authors of the new texts. To take just one example, John Buridan wrote a comprehensive textbook, commentaries on parts of Aristotle's Organon, and separate treatises on consequences and sophismata, the last containing a noteworthy treatment of insolubles.

4 The nature of logic

The purpose of logic had nothing to do with the setting up of formal systems or the metalogical analysis of formal structures. Instead, it had a straightforwardly cognitive orientation. Everyone accepted the view that logic is about discriminating the true from the false by means of argument. This is why logic was essential to the speculative sciences, since it provided the instruments for finding truth and for proceeding from the known to the unknown.

The first problem with logic was what to call it. The name '*dialectica*' was most prevalent until the thirteenth century, when '*logica*' gained the upper hand. Both words have various associations. '*Dialectica*' in the broad sense just is logic, but the word also has three narrower senses: dialectic as the art of debate; dialectic as the art of finding material for arguments; and dialectic as a kind of reasoning which falls between demonstrative and sophistical reasoning. The first sense was appealed to by Roger Bacon when he said that logic as an art has to do with disputation. The second sense is associated with the discussion of Topics, the headings under which the material for arguments can be sorted. Because the study of Topics also included maxims, or self-evidently true generalizations, which could provide the warrant for different types of argument, there is a close link between Topics and argumentation. Hence, the third and most usual sense of *dialectica* had to do with topical or dialectical syllogisms as a part of logic. Medieval logicians treated Aristotle's distinction between dialectical and demonstrative syllogisms as an epistemological one concerning the status of their premises, so that dialectical syllogisms had the same formally valid structure as demonstrative syllogisms.

The problems associated with the word '*logica*' have to do with whether logic is a linguistic or a rational pursuit. Isidore of Seville noted that '*logica*' comes from the Greek word '*logos*' which can mean '*sermo*' (word) or '*ratio*' (reason). As a result logic could be called either a *scientia sermocinalis* (linguistic science) or a *scientia rationalis* (rational science). There were considerations supporting both titles. On the one hand, the Stoics had divided philosophy into natural, moral and rational, and the last was equated with logic which could then, as Boethius pointed out, be seen as both an instrument and a part of philosophy (see Stoicism). On the other hand, logic was one of the liberal arts (see Encyclopedists, medieval §1) and belonged to the *trivium*, along with rhetoric and grammar, which made it seem a linguistic science. This emphasis was intensified by the discovery of Arab logicians who included Aristotle's *Rhetoric* and *Poetics* in the Organon, or logical works, a classification accepted by Albert the Great and Aquinas, among others. Some logicians, such as William of Sherwood, preferred to call logic just a linguistic science, but many others in the thirteenth century, including Robert Kilwardby and St Bonaventure, called it both linguistic and rational.

In the late thirteenth and fourteenth centuries the notion of logic as a rational science only became predominant. This move was partly associated with the rediscovery of the *Posterior Analytics*, the new emphasis on demonstrative science, and the increased importance of the classification of science into practical and speculative,

along with the associated division of speculative science into natural philosophy, mathematics and divine science. Unlike the Stoic classification, this one offered no obvious place for logic. Some later logicians, including Ockham, Buridan and Albert of Saxony, classified logic as a practical science, but most preferred to think of it as speculative (though of course with practical applications). People then called logic a supporting science (*scientia adminiculativa*), subordinated to the three important sciences. The notion that logic was a tool directing reason in the acquisition of knowledge was one reason for calling it rational.

However, the most important reason for calling logic rational had to do with views about its subject matter, and here the influence of Avicenna is crucial, for it was Avicenna who had said that logic was about second intentions. Second intentions, often identified with beings of reason (*entia rationis*), are those higher level concepts we use to classify our concepts of things in the world, and they include such notions as genus, species, subject, predicate and syllogism. There were obvious ontological difficulties here, for one could argue that second intentions pick out special common objects including both universals and logical structures, and one could also argue that second intentions are just mental constructs reached through reflection on individual things and on actual pieces of discourse or writing. Nominalists and realists obviously disagreed on ontology, but this did not prevent such nominalists as Ockham from agreeing that logic deals with second intentions, and that the syllogism the logician considers is neither a thing in the world, nor a piece of writing or speaking. Some people preferred to say that logic was about things in the world as they fall under second intentions, and other people preferred to pick out some special second intention such as argumentation or the syllogism as the subject of logic, but there was still a strong consensus that the objects of logic are rational objects.

These remarks have to be balanced by the obvious fact that people reason in ordinary language, and that ordinary locutions are often vague, ambiguous or misleading. Medieval logicians spent an enormous amount of time on the analysis of ordinary Latin, not because they thought that logic was theoretically concerned with ordinary language, but because this was the only way to avoid fallacious reasoning. Indeed, the avoidance of fallacy is at the heart of all the new types of logical writing.

5 Syllogistic

Despite the new forms of logical writing, syllogistic remained basic, and the syllogism was generally regarded as the central form of argumentation, to which all other forms could be reduced. This view is a lot less restrictive than one might imagine, because of the general way in which 'syllogism' was defined. Following Aristotle, logicians wrote: 'A syllogism is an expression in which, when certain things have been asserted, something else must occur by means of the things which were asserted' (Peter of Spain, in Kretzmann and Stump 1988: 217). This definition encompassed modal syllogisms, syllogisms with singular terms (called 'expository syllogisms'), tensed syllogisms with past and future verbs, syllogisms with 'oblique' (or inflected) terms such as genitives (for example, 'Every man's donkeys are running, Brownie (the donkey) is a man's, therefore Brownie is running'), and syllogisms containing such exponible terms (see §8) as 'only' and 'except'.

The standard core of syllogistic included immediate inference as captured by the square of opposition, the rules of equipollence (for example, 'Not every man is running' is equivalent to 'Some man is not running'), the laws of conversion and contraposition, and the categorical syllogism itself, together with the laws of reduction which allow one to prove non-first-figure syllogisms on the basis of the first-figure syllogisms, treated as axioms, and some other rules including conversion. (For details, see Logic, ancient.) The main medieval contribution here was the provision of mnemonic devices, particularly the verse 'Barbara, Celarent,…', which accounts for nineteen valid categorical syllogisms, together with detailed rules of reduction (see Peter of Spain, in Kretzmann and Stump 1988: 224-5).

One topic of discussion was whether a fourth figure should be recognized. This question relates to the ways in which the major and minor terms can be defined. From the sixteenth century onward, it became more usual to adopt the definition of Philoponus and to say that the major term is the predicate of the conclusion, while the minor term is the subject of the conclusion. This definition gives four figures which represent four possible arrangements of the major, minor and middle terms in two differentiated premises. Alternatively, if one adopts the standard medieval definition, whereby the major term is the term that appears with the middle term in the first premise, one can still speak of four figures with differentiated premises but it turns out that each figure also has indirect modes, in which the major term is the subject of the conclusion. The normal medieval account encompassed just the direct

and indirect modes of the first figure, and the direct modes of the second and third figures. People argued that the fourth figure is just the first indirect figure with transposed premises, and they did not count this as involving a genuinely different disposition of the middle term. John Buridan seems to have been the first to realize (in rather brief remarks) that on the medieval account, one will still have four distinct figures, and that the direct modes of the first figure will count as the indirect modes of the fourth figure in just the same way as the direct modes of the fourth figure count as the indirect modes of the first.

Another subject of discussion concerned the relation of perfect and imperfect syllogisms. ‘Perfect’ syllogisms were first-figure syllogisms whose necessity was obvious, and so needed no proof in terms of simpler argument forms, though they can be said to be founded on the regulative principles *dici de omni* (which ‘occurs when nothing is to be subsumed under the subject of which the predicate is not said’) and *dici de nullo* (which ‘occurs when nothing is to be subsumed under the subject from which the predicate is not removed’: Peter of Spain, in Kretzmann and Stump 1988: 217). Links between *dici de omni* and the Topic of quantitative whole were occasionally mentioned in the thirteenth century, but the general view was that perfect syllogisms do not need to be justified by appeal to Topics. Other syllogisms, however, are imperfect, and need to be justified by the rules of reduction, which involve the use of the laws of conversion. This immediately raises the problem of circularity, for if all arguments are reducible to the syllogism, it seems to follow that the laws of conversion are themselves reducible. There was considerable uncertainty on this point, and Burley, in his early treatise on consequences, says both that everything is reducible to the syllogism and that the laws of conversion are not. One way out of the impasse was to see the syllogism itself as just one among many forms of consequence (see §9), but although this is the approach taken by the later Burley and by Buridan, followed by Albert of Saxony, it is less prevalent than has often been suggested. Nor is there any reason to suppose that Burley or Buridan regarded themselves as showing that quantificational logic is based on propositional logic when they suggested that general inferences with unanalysed parts have some kind of priority.

The laws of contraposition raised an interesting semantic issue, which was discussed by Buridan and by various other logicians up to the early sixteenth century. It was commonly held that affirmative sentences with a non-referring subject were false, and the corresponding negative sentences true. But if one accepts term-negation while holding that sentences with term-negation (and no other) are affirmative, contraposition of the sort ‘All men are beings, therefore all non-beings are non-men’ will be invalid, given that there are no non-beings. Buridan and other late medieval logicians responded by claiming that the laws of contraposition could hold only when an extra existential premise was supplied. It is important to note a corollary of their view. In classical quantificational logic, the standard interpretation of sentences with non-referring terms is that universal sentences (formulated with ‘if…then’) are true, and particular ones (formulated with ‘and’) are false. As a result, quantificational formulations of the simple inferences ‘All *A*s are *B*, therefore some *A*s are *B*’ and ‘No *A* is *B*, therefore some *A*s are not *B*’ are rejected as invalid, as are the quantificational formulations of syllogisms with universal premises and particular conclusions. When medieval logicians had to decide on a uniform way of treating sentences with non-referring terms they decided not to draw a line between universal and particular sentences, but between affirmative and negative ones. As a result, the simple inferences captured in the square of opposition, the laws of equipollence, the laws of conversion and the standard categorical syllogisms remain valid. It is only the laws of contraposition that need reformulation.

6 Compounded and divided senses; modal logic

The discussion of modal logic is in part parallel to the discussion of categorical syllogistic. In general introductions to logic the discussion of modal propositions was followed by the discussion of simple modal inferences and equivalences as captured in a square of modal opposition, modal conversion and, finally, modal syllogisms. Buridan is noteworthy for the large number of modal equivalences he considered, and Ockham for his thorough exploration of different kinds of modal syllogism. Modal logic also figures in treatises on consequences, on proofs of terms, and on compounded and divided senses. The central modal notions employed were ‘necessary’, ‘impossible’, ‘possible’ and ‘contingent’, of which the last two need some explication. In the earlier period such logicians as Peter of Spain followed Boethius in treating ‘possible’ as equivalent to ‘contingent’, but later logicians, such as Buridan, made a careful distinction between ‘possible’ as compatible with ‘necessary’ but not with ‘impossible’, and ‘contingent’ as incompatible with both ‘necessary’ and ‘impossible’.

A full understanding of modal logic requires a consideration both of the basic tool of analysis, the distinction between compounded and divided senses, and also of the general theory of modality.

The distinction between compounded and divided senses has its origin in Aristotle's discussion of the fallacy of composition and division, to which Abelard was one of the first to pay careful attention. The basic point concerns two ways of reading the sentence 'A seated man can walk'. Interpreted according to its compounded sense, this proposition is *de dicto* (about a dictum or 'that' clause - see De re/de dicto §1) and means 'That-a-seated-man-walk (that is, while seated) is possible'. Interpreted according to its divided sense, the proposition is *de re* (about a *res* or thing), and means 'A seated man has the power or ability to walk'. The proposition is false in the first sense, but true in the second. It became standard when considering modal inferences in general and modal syllogisms in particular to distinguish between the compounded and divided senses of premises and conclusion, and to work out the logical results of these different readings.

In the fourteenth century the distinction between the compounded and divided senses was very widely used, as can be seen from the work of William Heytesbury, the first to devote a complete treatise to this topic. He listed nine types of logical problems which could be solved by paying attention to the distinction. These problems were signalled by the presence of modal words but also, for example, by the presence of future tense verbs, verbs producing confused supposition (see §7), terms such as 'infinite' which could be taken both categorematically and syncategorematically (see Oxford calculators §§2, 4), and words about acts of will and intellect. This last case ties in with epistemic logic, as a branch of applied modal logic. For instance, Heytesbury cites the inference 'Your father you believe to be a donkey; therefore, you believe your father to be a donkey' (Kretzmann and Stump 1988: 426-7), and remarks that it is invalid because the antecedent is taken in the divided sense ('Your father happens to be the thing [at a distance] that you take to be a donkey': true) and the consequent is to be taken in the compounded sense ('You believe that your father is a donkey': false).

The general theory of modality underwent interesting changes during the Middle Ages. In the earlier period, there were two possible approaches. On one approach, the interpretation of modalities is straightforwardly ontological and possibility is seen as a potency, an aspect of beings and events to be discussed in the context of change and motion. A second interpretation of modalities is the so-called statistical interpretation. On this account, to say that an object or state of affairs is necessary is to say that it occurs at all times, to say that it is possible is to say that it occurs at some but not all times, and to say that it is impossible is to say that it never occurs. For both these views, to talk about modalities is just to talk about what exists or occurs at various times, and modality is not some feature of the world over and above what there is. Moreover, they are tied to the principle of the necessity of the present, that is, that if *P* is true at time *t*, then it is not possible for not-*P* to be true at time *t*. An alternative model of possibility was at first confined to purely theological contexts, but in the twelfth century such authors as Gilbert of Poitiers and Abelard began to take a new approach, and in the fourteenth century Duns Scotus worked out the full philosophical implications of the alternative model, the so-called synchronic interpretation. On this model, possibility involves reference, not just to the present state of affairs, or to the potentialities of objects, but to states of affairs or worlds which are here and now alternative to the present world. There is no necessity of the present, and the basic notion is that of conceptual consistency. This new view leads to more complete and satisfactory formulations of the relations between modal sentences, especially when they are taken in the divided sense.

7 Supposition theory

The most notable new theory that took shape in the twelfth century was supposition theory and its ramifications, particularly ampliation and restriction. In the early period, *suppositio* was taken to be a property of a substantive term, while *copulatio* was a property of an adjectival term, and *appellatio* a property of a term that referred to actual existents. Later, the term *copulatio* was dropped, and *appellatio* acquired a totally new meaning (see below). Roughly speaking, supposition theory concerned what a categorical term (the subject or predicate of a proposition) can be taken to stand for in a particular context, and it was used to diagnose fallacies and test inferences.

The three main types of supposition were material, simple and personal. A term was said to have 'material' supposition when it stood for itself or its equiforms, as in 'Man is a noun'. Material supposition took the place of twentieth-century quotation devices, and gave rise to the same sorts of problems. A term was said to have 'simple' supposition when it stood for a universal, as in 'Man is a species', but this type was controversial, and not only because the question of the nature of universals is itself highly controversial. Peter of Spain suggested that

nouns used as predicates, such as ‘animal’ in ‘Every man is an animal’, had simple supposition, and William Arnaud in the late thirteenth century suggested that singular terms, such as ‘Socrates’ in ‘Socrates is an individual’, had simple supposition. These views were not generally accepted. Finally, a term has ‘personal’ supposition when it is taken for its normal referents, as when ‘man’ is taken for Socrates, Plato and so on.

Some logicians distinguished accidental personal supposition from natural supposition which allowed a term to have pre-propositional reference to all its referents, past, present and future, while others insisted that supposition must be purely propositional and contextual. This debate in turn affects the doctrines of ‘ampliation’, whereby the reference of a term can be extended, and ‘restriction’ (the opposite). Parisian logicians, such as Jean le Page (writing *c.*1235), tended to accept natural supposition, and to say (like Buridan in the fourteenth century) that terms had natural supposition in scientific propositions - that is, universal necessary truths - so that no ampliation was necessary. As a corollary, in non-scientific propositions the supposition of terms was restricted in various ways. For English logicians in the thirteenth century, all supposition was contextual, and the notion of ampliation had to be used when the subject of a proposition was to extend beyond present existent things. Both groups agreed that modal terms were particularly apt to produce ampliation. For instance, in ‘A man can run’, ‘man’ is ampliated to supposit for present and future men (Lambert of Lagny, mistakenly called ‘of Auxerre’, in Kretzmann and Stump 1988: 117).

The three types of personal supposition most often appealed to are determinate, purely confused (*confuse tantum*), and confused and distributive. These types were normally illustrated by means of the descent to singulars. For instance, to say that the subject of a particular affirmative proposition, ‘Some *A* is *B*’, has ‘determinate’ supposition is to say that one can infer the disjunction of singular propositions, ‘This *A* is *B*, or that *A* is *B*, or the other *A* is *B*,…’. To say that the predicate of a universal affirmative proposition, ‘Every *A* is *B*’, has ‘purely confused’ supposition is to say that one can infer a proposition with a disjoint predicate, ‘Every *A* is this *B* or that *B* or the other *B*,…’. To say that the subject of a universal affirmative proposition has ‘confused and distributive’ supposition is to say that one can infer a conjunction of propositions, ‘This *A* is *B*, and that *A* is *B*, and the other *A* is *B*,…’.

Some people distinguished between mobile and immobile cases. For instance, no descent is possible from ‘Only every *A* is *B*’, and so *A* has ‘immobile’ supposition. A fourth type of supposition is ‘collective’ supposition, as in ‘Every man is hauling a boat’, given that they are doing it together. Here any descent will involve a conjoint subject, as in ‘This man and that man and the other man…are all hauling a boat’.

The theory of personal supposition was used to solve a variety of problems. Some involved tense (for example, how to convert the proposition ‘No old man will be a boy’); some involved multiple quantification (for example, how to distinguish ‘Every donkey of some man is running’ from ‘Some donkey of every man is running’, to take an early sixteenth-century example); and some involved such verbs as ‘promise’, as in ‘I promise you a horse’. How such sentences should be analysed, and what kinds of inferences they could figure in, elicited a variety of complex solutions. The positions adopted included these: Heytesbury took it that ‘horse’ had purely confused supposition; Paul of Venice added that the supposition was immobile; and Buridan appealed to the new doctrine of appellation, according to which some verbs appellate a form, that is, bring into play the notion of something coming under a certain description. Ockham preferred to replace the sentence by a more complex sentence, ‘You will have one horse by means of my gift’. This solution is closer to the type found in treatises on the proofs of terms, which focused, not on the reference of the term ‘horse’, but on the analysis of the word ‘promise’ in terms of giving a right to an object.

8 Syncategoremata; proofs of terms

Supposition theory concerned the reference of the subject and predicate terms in propositions; treatises on syncategoremata dealt with all the other terms, such as ‘all’, ‘some’, ‘not’, which appear in a proposition and exercise some logical function. The two areas of investigation were very closely associated. Not only are there terms such as ‘infinite’ which can be interpreted both as categorematic and as syncategorematic, but some terms were dealt with in each type of treatise. For instance, in the first half of the thirteenth century the word ‘all’ or ‘every’ (*omnis*) was discussed in the tracts on distribution associated with supposition theory in the textbooks of Jean le Page, Peter of Spain and Nicholas of Paris, but in the treatises on syncategoremata by the Englishmen William of Sherwood and Robert Bacon. Peter of Spain and Nicholas of Paris both wrote treatises on

syncategoremata in which '*omnis*' is not discussed. As was noted above (§2) these works were very closely associated with those on sophismata.

Treatises on syncategoremata were most prominent in the thirteenth century, and they did not altogether disappear in the fourteenth. For instance, the late-fourteenth-century English logician, Richard Lavenham, wrote one. However, two other forms of writing come to the fore. First, there are a lot of short treatises on particular syncategorematic terms, including 'know' (*scire*), 'begins' (*incipit*) and 'ceases' (*desinit*), and terms with the power of producing purely confused supposition. Second, and most important, are the treatises on the proofs of terms (or proofs of propositions), whose best-known example is the *Speculum puerorum* of Richard Billingham, an Oxford author of the mid-fourteenth century.

In this context, a proof seems to be a method of clarifying a sentence containing a particular sort of term, or of showing how one might justify that sentence. There were three groups of terms. 'Resoluble' terms are those whose presence calls for explanation or clarification through ostensive reference, as captured in an expository syllogism (that is, one with singular terms). Thus 'A man runs' is resolved into the expository syllogism 'This runs; and this is a man; therefore a man runs'. 'Exponible' terms are those whose presence calls for exposition of the sentence in terms of a set of equivalent sentences. For instance, the sentence 'Only a man is running', which contains the exclusive term 'only', is expounded as 'A man is running and nothing other than a man is running'. Other exponible terms are exceptives, such as 'except', reduplicatives, such as 'inasmuch as', 'begins' and 'ceases', 'infinite', and so on. In fact, they are the terms which had figured prominently in treatises on syncategoremata. Finally, there are 'official' (*officiales*) or 'officiable' (*officiabiles*) terms, so called because they performed a function (*officium*). These included any term that governed a whole sentence or that treated a whole sentence as modifiable, such as modal terms, and such terms as 'know', 'believe', 'promise', 'desire' and 'owe'. Analysis of sentences containing such terms shows why they are referentially opaque when taken in the compounded sense.

Treatises on proofs of terms were very popular during the late fourteenth and fifteenth centuries, but they were joined by treatises which dealt with exponible terms alone. Pierre d'Ailly wrote one such treatise, and several were written in the early sixteenth century.

9 Consequences

The notion of '*consequentia*' was already discussed in the context of conditional statements by Garlandus Compotista, who wrote in the eleventh century, and was heavily influenced by Boethius' work on hypothetical syllogisms and on Topics. However, it was not until the beginning of the fourteenth century that consequences became the subject of separate studies, one of the very earliest being written by Walter Burley around 1300. The origin of these treatises is controversial. It has been argued that consequences grew out of the study of Topics, especially topical maxims (see §4), but there is no sign of a theory of consequences in thirteenth-century works on Topics, and very little in thirteenth-century commentaries on the *Prior Analytics* or the *Sophistical Refutations*, both places where discussion might be expected. There is some evidence of relevant discussion in treatises on syncategorematic terms, especially under '*si*' (if…then), but it seems most likely that ordered treatment grew out of the English desire to produce lists of rules for use in disputations about sophismata. This ties in with the strong orientation of many fourteenth-century English treatises towards syncategorematic terms. A small group of authors, including Ockham and the later Burley, did produce treatises between about 1325 and 1340 which are more oriented towards Topics, but these constitute a minority treatment. The rare Continental treatises, such as that of John Buridan (*c.*1335), had more to do with syllogistic than with syncategoremata. English treatises, especially those by such later fourteenth-century authors as Ralph Strode and Richard Ferribrigge, were used and commented on in the fifteenth century in Germany and Italy.

One problem to do with consequences is the relationship between a *consequentia* and a conditional statement. Unlike modern logicians who make sharp distinctions between syntax (what the rules allow one to infer) and semantics (validity), and between language (statements) and metalanguage (statements about statements), medieval logicians seem to have been indifferent about whether to present consequences as rules of inference, as arguments which may be valid or invalid, or as conditional statements. Buridan, for instance, defined a consequence as a hypothetical (that is, compound) proposition, and said that a good consequence could be called true or valid. The standard remark that all true conditionals are necessary, and all false ones impossible, strengthened the tendency to equate consequences and conditionals, as did the use of 'antecedent' to refer to the conjunction of the members of

the set of premises and ‘consequent’ to refer to the conclusion of a consequence.

Another problem concerns the definition of validity. The claim that a consequence is valid if and only if it is impossible for the consequent to be false when the antecedent is true was questioned for two reasons. In the first place, the propositions involved were taken to be occurrent items, whether written, spoken or mental. They could fail to exist, in which case there is nothing to carry a truth-value. Alternatively, their meaning could be at odds with their actual expression, as in ‘Every proposition is affirmative, therefore no proposition is negative’. Such problems were discussed at length, for example, by Buridan, who solved them by substituting a definition in terms of signification, that is, that a consequence is valid if and only if it is impossible for it to be as signified by the antecedent without its being as signified by the consequent.

The presence of ‘if and only if’ raises the second problem. The truth definition (or Buridan’s substitute) may provide a necessary condition for validity, but is it sufficient? If it is sufficient, then we must accept the paradoxes of strict implication, that is, that anything follows from an impossible proposition, and a necessary proposition follows from anything. The debate about these paradoxes began in the twelfth century, and there was a series of attempts to provide a second condition which, with the first, would be sufficient for validity. Abelard had a containment principle by which the dictum of the antecedent should contain the dictum of the consequent (see Abelard, P. §4), and Robert Kilwardby in the next century, like Strode in mid-fourteenth-century Oxford, said that the consequent had to be understood in the antecedent. Some people in the thirteenth century focused on reality, and argued that a consequence must capture a causal relation, and that as a result the antecedent must be about a state of affairs that can at least be supposed to be possible. None of these people could accept the paradoxes as formally valid. On the other hand, the Parvipontani or Adamites (followers of Adam of Balsham) in the twelfth century and Buridan in the fourteenth were happy to accept the first clause as offering both necessary and sufficient conditions for validity, with all that that implied for the acceptance of the paradoxes.

One favourite division of consequences, found in such authors as William of Sherwood and Robert Kilwardby, was into natural and accidental (or non-natural) consequences. A natural consequence met the two-clause condition for validity, and an accidental one did not. The paradoxes could then be classified as accidental consequences. Later authors tended to make a division into formal and material consequences, but we have to be careful here, as there were two approaches to the notion of material consequence. For some, a material consequence involved the independence of antecedent and consequent, and just was the two paradoxes. For others, such as Buridan, a materially valid consequence is defined as one which does not hold for all terms arranged in the same way, and includes such enthymemes as ‘If all animals are running, then all humans are running’.

Another division of consequences is into those valid absolutely (*simpliciter*) and those valid as of now (*ut nunc*). This division, which appears in Ockham, has been much discussed, though it is in fact relatively rare, at least in fourteenth-century English treatises. Consequences valid *ut nunc* have been thought to correspond to the modern material conditional, but this is not so, as modal notions are definitely involved. Given that Socrates may not exist, and given that sentences with non-existent subjects are held to be false, ‘If all men are running, then Socrates is running’ is not generally valid. However, if Socrates does exist, then it is impossible for the antecedent to be true and the conclusion false, and we have a consequence which is valid as of now.

The question of the paradoxes also leads us to the question of the relationship between consequences and propositional logic, as discussion of the paradoxes provided one of the main occasions for sequences of rules to be used in a proof. The typical sequence was as follows: from the contradiction ‘*P* and not-*P*’ we can infer *P*, and from *P* we can infer ‘*P* or *Q*’. From ‘*P* and not-*P*’ we can also infer not-*P*, and from ‘*P* or *Q* and not-*P*’ we can infer *Q*. Hence, from ‘*P* and not-*P*’ we can infer *Q*. This sequence is found in the twelfth-century theologian Alexander Neckham, and it reappears through the centuries. But the explanations given differ widely. In his treatise on syncategoremata, Peter of Spain appealed to topical maxims, and claimed more generally that we need topical maxims as a foundation for consequences. On the other hand, in Pseudo-Scotus, writing *c*.1350, we get an appeal to what seem to be straightforward rules of propositional logic.

It has been claimed that later treatments of consequences showed that medieval logicians grasped that quantificational logic is founded on propositional logic, but this is anachronistic. Texts on consequences contain a mixture of rules (from the point of view of the modern logician, that is). Some are general (‘If *A* is the antecedent of *B*, and *B* is the antecedent of *C*, then *A* is the antecedent of *C*’). Some are propositional and truth-functional

('Since a conjunction is true if and only if its conjuncts are true, from ''*A* and *B*'' we may infer *A*'). *Modus ponens*, *modus tollens* and De Morgan's rules are given. Other rules are syllogistic; yet others are modal. Medieval logicians had no interest in classifying rules according to different formal systems, since they did not operate with the notion of a formal system in the first place.

10 Insolubles

'Insolubles' (*insolubilia*), so-called, it was claimed, because they are difficult to solve rather than completely insoluble, are semantic paradoxes. The simplest version is the liar paradox, 'What I am saying is false', given the *casus* or initial situation that this is all that is said, but complex versions with hypothetical propositions ('God exists, and some conjunctive proposition is false') or sequences of mutually referring propositions ('Suppose that Socrates says ''Plato says something false'', and Plato says ''Socrates says something true''' - Albert of Saxony, in Kretzmann and Stump 1988: 357, 349) were also discussed. In the twentieth century such paradoxes have been used to cast doubt on the very foundations of semantic theory, and have led to elaborate distinctions between levels of language and metalanguage. Medieval logicians, however, showed no signs of such a crisis mentality, and while they did employ certain restrictions on self-reference, and make certain distinctions between language and metalanguage, these techniques were generally limited to the problem in hand.

A very early formulation of the liar paradox is found in Adam of Balsham, writing in 1132, and later in the twelfth century Alexander Neckham gives a formulation. Full discussion seems to have started at least by the second half of the twelfth century, and continued until the sixteenth century. In the early period insolubles seem to have been discussed in the framework of Aristotle's *Sophistical Refutations*, and after that, within the general framework of a sophismatic disputation. From about 1320 to 1350 there was a period of intense and sophisticated activity, during which new solutions were given, and the framework of an obligational disputation was used (see §11). After 1350 some authors, such as John Wyclif and Pierre d'Ailly, still had original solutions to offer, but most authors, including Paul of Venice, merely elaborated previous ones.

The early solutions to the paradox include 'restriction', which forbids self-reference, either by saying that a part ('false') cannot supposit for a whole ('I say what is false'), or by saying that 'I say' cannot refer to the present moment; and '*cassatio*', according to which a paradox says nothing at all. The first major new solution was that of Thomas Bradwardine (*c.*1320-4). Bradwardine claims that propositions signify whatever follows from them and that insolubles signify that they are true. As a result, an insoluble signifies that it is true, but it is true if and only if it is both true and false. This cannot be, so it is false. John Buridan (§2) and Albert of Saxony both follow Bradwardine. Roger Swyneshed was author of another popular solution. He said that truth requires not just correspondence with reality but also absence of self-falsification, and Paul of Venice gives a version of this solution in his *Logica Magna*.

11 Obligations

Treatises on 'obligations' discussed the rules for obligational disputations, which were logical exercises for students. They got their title because of the rules obliging one to answer in a certain way. Obligational terminology is found in the late twelfth century, and the theory was already well-advanced in Paris by 1240-50. In 1302 Walter Burley wrote a treatise which summarized much previous material, and laid the foundations for later developments. Other important treatises were by Roger Swyneshed (1330-5), Ralph Strode and Marsilius of Inghen. The terminology of obligational disputation, including the use of a *casus* or description of the initial situation, permeated much fourteenth-century writing, including theology.

Various types of obligational disputation were discussed. One classification, which has thirteenth-century origins and was popularized by Marsilius of Inghen in the second half of the fourteenth century, related to the three legitimate ways of responding: '*concedo*' or 'I grant it'; '*nego*' or 'I deny it'; and '*dubito*' or 'I doubt it'. Walter Burley had six types, including '*impositio*', in which words and sentences were given new meanings for the duration of the disputation.

The most important of the different types of obligational disputation was '*positio*'. In this type of disputation, the opponent began the game by positing a proposition which the respondent had to grant, provided that it was logically possible. This *positum* was normally false, and it was usually trivial in content. Next the opponent had to

propose a series of other propositions, which could be either true or false. In replying to these, the respondent had to follow the rules of the game. If a proposition followed from the set formed by the *positum*, the propositions already granted and the negations of propositions already denied, it had to be granted. If a proposition was inconsistent with the set so determined, it had to be denied. If a proposition was such that neither it nor its negation followed from the set so determined, it was called *impertinens* or irrelevant, and the respondent had to reply to it according to his current state of knowledge. The task of the opponent in this game was to lead the respondent to the point of accepting an inconsistent set, either by granting and denying the same proposition, or by granting a proposition whose negation would follow from the set of propositions already granted. The task of the respondent, of course, was to avoid falling into these traps. In order to be successful, the respondent needed an excellent grasp of the logical relations between propositions and also an excellent memory. This is why obligational disputations could serve as valuable exercises for young logicians.

Some changes are reflected in the treatises. In the early period, impossible *positio* was very important, and still occurs in Ockham, though very rarely afterwards. In this kind of disputation, one begins with an impossible proposition which can at least be conceived to be true, a condition which excluded the use of explicit contradictions. Another change related to developments in modal logic. In the thirteenth century, the respondent had to deny that the actual 'now' of disputation was the instant at which the false but possible *positum* is treated as true, and as a result the replies to irrelevant propositions were related to actual time, while the replies to relevant propositions were related to an imaginary time. Once the notion of synchronic alternatives to the actual world had been adopted, all replies could be related to the same time. In the later period, Roger Swyneshed altered the relationship between irrelevant propositions and the *positum*. In the usual rules, once an irrelevant proposition had been admitted into the sequence, it (or its negation) became relevant. For Swyneshed, relevance was strictly a matter of a relation between the *positum* and those propositions that follow from or are incompatible with it alone. This produces two separate sets of responses, one involving relevant propositions, and one involving irrelevant propositions. As a result, one can deny a conjunction both of whose parts have been granted, and grant a disjunction both of whose parts have been denied. This view generated a good deal of discussion in the fourteenth and fifteenth centuries, and was usually rejected.

The biggest problem presented by treatises on obligations has to do with their purpose. They were certainly closely connected with consequences, insolubles and sophismata. Equally certainly they were closely connected with undergraduate training. Among other possibilities, it has been suggested that they also presented theories of counter-factual conditionals, or that they represented thought-experiments in which retrospective construction of a possible world takes place.

Logic, philosophy of

Philosophy of logic can be roughly characterized as those philosophical topics which have emerged either from the technical development of symbolic (mathematical) logic, or from the motivations that logicians have offered for their technical pursuits. In settling on a list of subjects to classify as philosophy of logic, therefore, there is a certain degree of arbitrariness, since the issues which emerge from the technical development of logic can equally well be assigned to such areas as semantics, philosophy of language, philosophy of mathematics, epistemology, and even ethics (see Semantics; Language, philosophy of; Mathematics, foundations of).

1 The impact of modal logic

In the broad area of mathematical logic, the biggest philosophical punch is packed by modal logic, including tense logic (see Modal logic; Modal logic, philosophical issues in; Tense and temporal logic). Modal logic has been important since Aristotle (see Logic, ancient; Logic in the 17th and 18th centuries; Logic in the 19th century; Logic in the early 20th century) but has only been put on a rigorous footing in the second half of the twentieth century, by such figures as Hintikka, Kanger, Prior, and most especially Kripke (see Semantics, possible worlds). The most important philosophical outgrowth of this mathematical work is contained in Kripke's three lectures from January 1970 published as 'Naming and Necessity', in which Kripke draws out some ways in which possible worlds semantics is in tension with then-prevailing orthodoxies in the philosophy of language and mind. Some of Kripke's views have become new orthodoxies since (see Essentialism; Proper names; Reference §§2-4; for related work by David Lewis, Robert Stalnaker, David Kaplan and others that uses the possible worlds framework, see Counterfactual conditionals; Demonstratives and indexicals; Descriptions).

To give some flavour of developments here, consider the familiar Fregean view that the relation of *reference* which holds between a name and its bearer is sustained by the relation of *presentation* which holds between the *sense* of the name and the bearer of the name: the name refers to such-and-such an object precisely because it expresses a sense which presents that object (see Frege, G. §3; Sense and reference). When pressed for an explanation of what the senses of names are like, the natural Fregean response is to specify them, as Frege himself did in some cases, using definite descriptions (see Descriptions). So, for instance, the sense of the name 'Aristotle' might be 'the pupil of Plato who taught Alexander'. However, though it may well in fact have been Aristotle who taught Alexander, there are many ways things might have gone (many 'possible worlds') in which someone other than Aristotle is taught by Plato and teaches Alexander: suppose Aristotle had got the appointment but been killed in an accident before he could take it up, and had been replaced at Philip's insistence by another pupil of Plato. The description 'the pupil of Plato who taught Alexander' is therefore 'non-rigid', in Kripke's terminology. That is, it can pick out different individuals in different possible worlds, and in some worlds may pick out no one (Philip for some reason comes to distrust Platonic pedagogy and fails to conduct an equal opportunity search). But it is clear from the formal semantics for modal logic that there is conceptual 'room' for a category of expression which is 'rigid', in the sense that it picks out the same object in every possible world, or at least in every possible world where it picks out any object at all. So the formal semantics prompts the question whether names in natural language behave as if their reference is determined by a sense which presents different individuals at different worlds, or whether they behave as if they are rigid designators. With a series of brilliant examples Kripke demonstrates that names are rigid designators and therefore do not express reference-determining senses which are non-rigid (see Proper names).

The idea that a formal semantics for a kind of logic provides an account of a possible semantics for a category of natural-language expression, opening the door to debate on whether it is the right account or not, also captures some of the philosophical bearing of kinds of logic other than modal logic. Thus free logic shows how name-like expressions can function without standard existential commitment (see Free logics, philosophical issues in); intuitionistic logic and many-valued logic show how a language can have a compositional semantics even if its sentences are not used to make statements with verification-transcendent truth-conditions which always either obtain or fail to obtain (see Compositionality; Intuitionistic logic and antirealism; Many-valued logics, philosophical issues in; Presupposition). And second-order logic offers a particular way of understanding the semantic import of a range of puzzling locutions, such as plural quantifiers (see Second-order logic, philosophical issues in). In all these cases the formal semantics for the logical system prompts debates about how well the

semantics carries over to natural language.

2 Logic and language

There is also a collection of long-established topics discussion of which can be much improved, in rigour at least, in the light of the development of modern logic. For example, a distinction between propositions (or statements, or sentential contexts) which are *de dicto* and propositions (and so on) which are *de re* originates in medieval philosophy. But only contemporary modal logic affords the tools for a precise characterization of this distinction, although it must be granted that the distinction remains a puzzle in *epistemic* contexts (see De re/de dicto; Descriptions §2; Propositional attitude statements). Other topics which can be classified in this way include Essentialism, Existence, Identity, Indicative conditionals, Modal operators, Quantifiers and Vagueness. Again, to give some of the flavour of this kind of work, consider the *de re*/*de dicto* contrast. There is an evident syntactic difference between ‘It is necessary that parents have children’ and ‘Parents are such that it is necessary that they have children’, but just because there is a syntactic difference, it does not follow that there is any interesting difference in meaning. But the difference can be brought out quite precisely in possible worlds semantics. To say that it is necessary that parents have children is to say that in every possible world, the people who are parents *in that world* have children in that world; and this is an obvious truth. On the other hand, to say that parents are such that it is necessary that they have children is to say that the people who are parents *in the actual world* are such that they have children in every possible world. This is clearly false, even putting aside contingency of existence of actual parents. For given anyone who is actually a parent, there is a way things could have gone - a possible world - in which that person is childless, hence not a parent (see Quantifiers, substitutional and objectual; Modal operators).

When a formal semantics for a system of logic is applied to a fragment of natural language, a very precise account of the literal content of sentences in that fragment is given. But there may be aspects of the meanings of those sentences which are omitted. Philosophical views may then divide over whether the formal semantics has been shown to be wanting as an account of the semantics of the fragment, or whether instead the aspects of meaning not captured have been shown not to belong to literal content (see Presupposition). In the case of indicative conditionals, for instance, the formal semantics that is relevant is the simplest possible kind, namely, the truth-functional account of ‘if…then…’. According to this account, ‘If *p* then *q*’ is true if *p* is false or if *q* is true, regardless of the actual meanings of *p* and *q*. So in particular, any indicative conditional with a true consequent is true; examples would include ‘If lead floats in water then lead sinks in water’ and ‘If the solar system has nine planets then the Conservative Party lost the British elections in 1997’. Barring an astrological justification of the latter, both these conditionals look decidedly odd. But oddness is one thing, falsity another. The idea that such conditionals are false is based on the thought that if a conditional is true, then in establishing it in the most direct manner, non-redundant use has to be made of the antecedent. Spelling this out leads to relevance logic (see Relevance logic and entailment; Indicative conditionals). On the other hand, if we say the conditionals are merely odd, we are led to some theory of communication to explain the oddness (see Grice, H.P.; Implicature).

But we should not take away the impression that the traffic is all one way, from logic to language or from pure mathematics to pure philosophy. There is a two-way street here, with the above comments on conditionals representing a common phenomenon; that of a concern in the philosophy of language giving rise to a formal development which in turn feeds back into philosophy. For example, the idea that for a conditional to be true, the most direct way of establishing it must make non-redundant use of its antecedent seems clear enough on the face of it, but familiarity with logic of conditionals literature may well lead one to reconsider. This kind of dialectical interplay should continue to be a fruitful source of philosophical research for the foreseeable future.

Logic, Renaissance

Renaissance logic is often identified with humanist logic, which is in some ways closer to rhetoric than to the study of formal argumentation. This is a mistake, for although changes did take place, a hard core of logical teaching remained the same throughout the medieval and Renaissance periods and into the eighteenth century. Logic was embedded in the educational system as the main study of beginning undergraduates, and although institutional changes had an effect on the presentation and use of logic texts, the study of valid arguments was always central.

There are two obvious differences between medieval texts and their sixteenth-century successors. The first is a new emphasis on following the order and material of Aristotle's Organon*, with the consequent emphasis on the categorical syllogism as the central type of argument. Such medieval material as survived was strictly subordinated to this end; and even though the humanist logicians Agricola and Ramus had tried to ignore Aristotelian syllogistic and the doctrines propaedeutic to it (such as conversion and opposition), their omissions were rapidly remedied by subsequent textbook writers.*

The second difference has to do with language and style. Medieval writers treated Latin as a technical, almost artificial language. They were deeply concerned with the effects that different word-orders and the addition of extra logical particles had on both meaning and reference, and they made heavy use of sophismata*, deliberately constructed problematic or puzzling sentences. Although Latin remained the language of instruction, the approach of a Renaissance logician, whether humanist or Aristotelian, commentator or textbook writer, is totally different.* Sophismata *have completely disappeared, and so too has any attempt to treat Latin as a technical language in which different word-orders represent different logical structures. The propositions used for such operations as syllogistic conversion are presented in an already fully standardized form, and they are always relatively simple.*

Why these changes came about is a difficult question. Humanism coexisted too long with medieval logic for humanism to be the sole explanation, and the fact that Renaissance logicians returned to the commentaries of Averroes and Aquinas on the Organon shows that mere revolt against anything medieval is not a sufficient explanation either. Changes in grammar teaching, changes in the relation of logic to the study of natural science, and changes in other parts of the university curriculum presumably have a good deal to do with the appearance of a new style of logic. In particular, the humanist emphasis on logic as a tool for analysing discourse focused attention on the use of logic in literature, history and biblical studies, and demanded a combination of simplicity and literary elegance, rather than any genuine formal innovation. There was no concurrent move to relate logic to the new developments in mathematics, and logic was not to be seen as a formal system linked with other formal systems until the nineteenth century.

1 The nature and divisions of logic

One of the features distinguishing sixteenth-century textbooks, whatever their orientation, from their medieval predecessors was their approach to the nature and divisions of logic. Medieval authors had asked whether logic is more properly a linguistic discipline directed towards spoken words (*scientia sermocinalis*) or a rational discipline directed towards concepts (*scientia rationalis*), and this question did not disappear (see Logic, medieval §4). However, its presentation was to some extent altered. The influence of the humanists, especially Agricola, gave general popularity to Cicero's definition (*Topics* II 6) of logic as an art of discourse (or *ratio disserendi*) (see Cicero §2), and this notion is also found in such scholastic authors as Toletus and Fonseca. At the same time, logic was frequently said to have as its subject either conceptual entities (beings of reason: *entia rationis*) (see John of St Thomas §2; Language, renaissance philosophy of §3), or second intentions (see Zabarella, J. §2). Toletus denied a distinction between these two notions in this context, on the grounds that to talk about the kind of conceptual entity which has no existence independently of the mind is just to talk about those second-order logical concepts or intentions (genus, species, syllogism and so on) which we use to organize first-order concepts, those which apply directly to things in the world.

One issue which was the subject of lively debate concerned the very use of the word *logica* as opposed to *dialectica*. It was a medieval commonplace that *dialectica* could be used in two senses, a broad sense which equated dialectic with logic, and a narrow sense, in which dialectic was the kind of probable argumentation discussed in Aristotle's *Topics* (see §4) (see Fonseca, P. da §2). In the sixteenth century, Ramus argued in his

Scholae (Lectures) that the division of logic into demonstrative, dialectical and sophistical reasoning is baseless, and that all logic is dialectic (see §4). Zabarella, on the other hand, believed that 'dialectic' did name a distinct part of logic, and should be reserved for that part alone.

Another issue which reflects the impact of humanism concerned the way in which logic was divided. Perhaps the most important division was that into invention and judgment, invention being the part of logic which finds the subject matter for argumentation, and judgment being the part which organizes the subject matter. This division came principally from Cicero (*Topics* II 6) and was well known to medieval logicians, before it was further popularized by Agricola, Melanchthon and Ramus. A mark of Ramist textbooks was that they began with invention, but Melanchthon, followed by various authors including John Seton (see §5) put judgment first. Another way of organizing which was to become especially popular in the seventeenth century (see John of St Thomas §2; Logic in the 17th and 18th centuries §1) was a division in accordance with the three acts of mind, the apprehension of simples (terms), composition and division (propositions), and reasoning (arguments). Like the division into invention and judgment, this division has a long history.

2 The medieval inheritance

Although Aristotle served as a focal point for the study of logic during the Middle Ages and Renaissance (see §3), one of the main features of medieval logic was the production of independent texts on particular topics, some of which had no reference to Aristotelian logic. The most important of these texts were the so-called *parva logicalia*, or treatises dealing with the properties of terms, including their reference in various contexts. Here we find tracts on supposition, on relative terms, on ampliation, appellation, restriction and distribution (see Logic, medieval §7). These core treatises were supplemented in various ways, particularly by treatises about exponible terms, those logical particles such as 'except' and 'only' whose presence calls for the analysis of an apparently simple categorical proposition into several conjoined propositions.

A second major group of treatises consisted of the 'three tracts of the moderns', which concern propositions and the relations between them. Here we find treatises on consequences, obligations and insolubles. Treatises on consequences covered all types of argumentation, beginning with a general discussion of what constitutes a formally valid inference, and including a good deal of propositional logic. The syllogism often appeared as a special example of one kind of argumentation. Treatises on obligations dealt with the rules to be followed in a certain kind of disputation which was specifically designed to test the logical skills of undergraduates, and which deliberately confined itself to exploring the logical consequences of affirming an often bizarre falsehood. Treatises on insolubles dealt with semantic paradoxes, such as the standard liar paradox, 'What I am now saying to you is false', and they explored in some depth the semantic presuppositions of language (see Semantic paradoxes and theories of truth).

During the fifteenth century much of this medieval material was used throughout Europe, and Italy was particularly enthusiastic about the products of fourteenth-century Oxford logicians, such as Heytesbury and Ralph Strode. *Summulae* or general textbooks from the earlier period were also used. The best known is by Peter of Spain, and it gives a fairly complete outline of Aristotelian logic as well as the *parva logicalia*. However, it would be a mistake to think that only Peter of Spain was used, for in some places (such as England) he was never used, and in other places only parts of his work were used. Buridan (§2), Albert of Saxony and Paul of Venice were the authors of other popular textbooks. Indeed, the first medieval logic text known to have been printed is Paul's *Logica parva*, printed in 1472 (and still being reprinted in Venice as late as 1614).

At the beginning of the sixteenth century, particularly in Paris, there was a strong revival of the medieval tradition. Separate treatises on supposition theory, exponibles, consequences, insolubles and obligations continued to be written (see Major, J. §2), and to these were added new treatises on such matters as terms and opposed propositions. At the same time, new commentaries on Peter of Spain were being published in Paris, Germany and Spain. The 1529 edition of Domingo de Soto's *Summulae* included commentary on the first and fourth books of Peter of Spain along with treatises dealing with terms and supposition theory, exponibles, insolubles, and obligations (see Soto, D. de).

Outside Spain, this activity came to an abrupt halt around 1530. No new independent treatises on Peter of Spain were written; the publication of works written during the first three decades of the sixteenth century ceased, and

the publication of such medieval authors as Buridan and Heytesbury also ceased. Only in Spain and its colonies did authors continue to produce commentaries on Peter of Spain, such as that by Alonso de la Vera Cruz, first published in Mexico in 1554, or that by Tomás Mercado, published in Seville in 1571 (see Latin America, colonial thought in §3; Mexico, philosophy in §1).

By the end of the sixteenth century those parts of medieval material which could not easily be integrated with Aristotelian logic simply disappeared, at best being the subject of stray and often unflattering references. Insolubles were no longer discussed, obligations were replaced by a discussion of ordinary disputations in which truth was the main issue, and many of the topics connected with supposition theory were dropped. But exponibles, consequences and the central part of supposition theory remained in truncated and simplified form (see §6).

3 Aristotle and Aristotelianism

At least in principle, Aristotle's Organon played a central role throughout the medieval and Renaissance period (see Aristotle §4), though not all parts were studied with equal fervour. For instance, the *Topics* was sometimes omitted altogether, and sometimes only certain of its books were assigned. The text of the Organon was accompanied by explanation and commentary, and the invention of printing brought the wide dissemination of some of the medieval commentaries on Aristotle's logical works, including those by Walter Burley and Paul of Venice. Later there was a return to commentaries by the great theologians of the thirteenth and early fourteenth centuries. Thus, the commentaries of Aquinas on *De interpretatione* and *Posterior Analytics* reached a peak of popularity in the mid-sixteenth century, and the commentaries by or attributed to Albert the Great (§2), Giles of Rome and John Duns Scotus were also published (see Aristotelianism, medieval §5). The great Giunta edition of Aristotle with the commentaries of Averroes (1550-2) should also be mentioned.

The impact of humanist classical studies on Renaissance logic is particularly important in two respects: first, the edition and translation of Greek commentators on Aristotle, only some of whom had been known during the Middle Ages; and second, the edition and translation of Aristotle himself. During the fifteenth century the Byzantine humanist and philosopher Johannes Argyropoulos (*c.*1415-87) had produced new Latin translations, but as the Greek text became better known, more and more dissatisfaction was felt with former translations, including those of Argyropoulos. A good example of the new Greek-based texts is the Organon edition of Giulio Pace first published in 1584. In it we find the Greek text side-by-side with a new translation designed not only to read well but also to capture the philosophical significance of Aristotle's words. In the margins there is a commentary dealing with difficult points both of theory and of translation. However, the old translations did not disappear, because they provided much of the standard vocabulary in philosophy, and the work of surviving medieval commentators was keyed to them (see Humanism, Renaissance).

So far as content is concerned, there were few developments within Aristotelian logic. There was considerable discussion of scientific method (see §7), and there was also some lively debate about the acceptability of the fourth figure of the syllogism, particularly inspired by Zabarella. Otherwise, Aristotelianism's main achievement was its successful stand against attempts such as those by Lorenzo Valla (§4) and Petrus Ramus to replace basic Aristotelian notions. This achievement was mainly due to the felt need for formal content in logic teaching (see §5) (see Aristotelianism, Renaissance §1).

4 Humanist logic and the topics

To understand humanist logic, one must consider the relations between dialectic, the topics, and rhetoric. 'Dialectic' is a term with various meanings. For those who did not use it as a mere synonym for logic, at least three approaches were possible. One could present dialectic as the study of debate or disputation; one could present dialectic as the study of the topics (roughly speaking, headings under which material could be gathered); or one could present dialectic as the study of probable argumentation.

The last two approaches are closely related to the concerns of rhetoric, and there is a tendency in the literature to speak as if humanist logic was the result of subordinating logic to rhetoric. However, while it is true that rhetoric texts featured the invention or finding of topics, and that rhetoric, as the art of persuasion, could be construed as dealing with arguments about probabilities, the three standard works about topics had always been firmly part of the logic syllabus. These were Aristotle's *Topics*, together with Boethius' two works, *De topicis differentiis (On*

Topical Differences) and *In Ciceronis Topica (On Cicero's Topics)* (see Boethius, A.M.S. §3). Boethius' first work was more important in the medieval period, though in the fourteenth century it was largely replaced by the account of topics given by Peter of Spain in his *Summulae*. In the sixteenth century Boethius' second work became popular again, as did Cicero's original text. Agricola himself was well-acquainted with both Aristotle and Boethius.

The notion that dialectic is concerned with probable argumentation comes from Aristotle's *Topics*, which opens with a distinction between demonstrative reasoning, said to deal with certainties, and dialectical reasoning, said to deal with probabilities. However, there are two ways of reading the distinction. One way involves two types of logic, a logic of formally valid deductive arguments, and a logic of informal arguments or strategies. The other way of reading Aristotle's distinction is to assume that 'argument' or 'reasoning' in the Topics refers only to the syllogism as described in the *Prior Analytics*, namely a particular kind of formally valid deductive structure. This second reading led medieval logicians to interpret Aristotle's distinction between demonstrative reasoning and dialectical reasoning as an epistemic one. Thus, demonstrative reasoning involves formal syllogisms with premises that are certainly true, and dialectical reasoning involves the same formal syllogisms with premises that are only probably true. It was this epistemic reading that led Ramus to argue that dialectic and logic are the same, since the same patterns of argumentation appear in both. In Agricola, on the other hand, we find a somewhat greater awareness of the possibility of a properly non-formal logic.

The general failure of humanist logicians, including Agricola, to pursue dialectic as an informal logic of probabilities was closely associated with their treatment of the other aspect of dialectic, dialectic as a topics-logic, or means of finding the material for arguments. In Boethius, the notion of a topic had covered two things. First, a topic was a maxim (or 'maximal proposition'), a self-evidently true universal generalization which could either be inserted into an argument as a premise or which could be appealed to as providing a warrant for an argument. Some of these maxims were themselves turned into formal deductive arguments by medieval logicians, who had a tendency to absorb invention into judgment, but others were not easily formalized. As such, they provide the perfect nucleus for a developed informal logic. The second sense of topic for Boethius was the topic as the *differentia* of a maximal proposition, that is, the characteristic that enables us to classify maximal propositions into groups. To list the topics in this second sense is simply to list the headings under which material can be gathered: 'definition', 'genus', 'cause', 'opposite', 'similar' and so on.

What we find in Agricola (§2) is a deliberate rejection of the maxims, and of material that might belong to judgment rather than invention. He argued that the purpose of any maxim is simply to present a necessary argument, and that they are quite inappropriate for all the cases in which we are dealing with probabilities. We should note here that Agricola is clearly talking not just of the epistemological status of the premises of an argument, but of a probabilistic and informal relationship between premises and conclusion. He also claimed that maxims were too restrictive, for they represent an attempt to force a wide range of material into a narrow compass; and that they are of no use to someone who really understands the nature of topics. What we are left with, then, is the topics solely as headings under which material can be organized. Their most obvious link with argumentation, both formal and informal, has been broken.

In the hands of Agricola's later follower, Petrus Ramus (§2), we find the topics presented in an Agricolan way, without maxims, but with a new theoretical foundation. They are not merely useful headings for gathering material, but they represent the mind's natural organization of data. As such, topics function as categories; and, indeed, Ramus emphasized that his topics are more useful and more natural than Aristotle's ten categories (see Categories §1). If we are asked to discuss war, peace, or the state, it is no use to think in terms of the category of substance. Instead we must appeal to such topics as cause, event and opposites.

The result of these reforms was a subordination of rhetoric to logic (rather than the reverse), in three respects. First, the topics were now to be confined to dialectic, and rhetorical topics, which had covered material of a more particular kind, were to be reduced to dialectical topics. Second, rhetoric's *dispositio* is introduced into the dialectic text through the discussion of method as a way of ordering discourse. Third, we find that rhetoric, at least in the eyes of the humanist logician, was to be confined to the business of ornamenting discourse, and discussing only those persuasive devices which did not involve argumentation.

5 Humanist and Ramist textbooks

The needs of the university curriculum meant that humanist insights and changes were only partially reflected in logic teaching. Thus Agricola’s seminal *De inventione dialectica* (see Agricola §2) was often used in conjunction with a little Aristotelian handbook by George of Trebizond. The very popular textbooks of Melanchthon provide another good example. He enjoyed the Agricolan emphasis on clarity of style and the use of literary allusions; he accepted the importance of the topics and the part of logic called invention; and he discussed method. At the same time, he remained a convinced Aristotelian, who believed that students needed to be taught some formal logic. The formal techniques he used were those of syllogistic, and his work included a discussion of the other standard Aristotelian logical subjects, including the categories and the square of opposition for propositions.

Another example from the first part of the sixteenth century is John Seton’s *Dialectica*, first published in England in 1545, and later to appear with annotations by Peter Carter. Seton explained in his introduction that he had written the work because of the absence of a suitable text for the instruction of the young. Aristotle was too difficult, Agricola had deliberately restricted himself to the subject of invention, and Melanchthon’s style was not suited to elementary teaching. He makes frequent references to Agricola, as well as to Cicero, Quintilian and Erasmus. He included the bulk of traditional Aristotelian logic from the categories to the syllogism, which he described as the most important part of judgment, and he also retained the strictly medieval doctrine of the supposition of terms, though in a considerably truncated form.

In the second part of the century the most important textbook writer was Petrus Ramus (§2), the most notorious logician of the period. He is known both for his attacks on Aristotle and for the simplified logic presented in his *Dialectique* of 1555, and in a variety of Latin versions. The *Dialectique* had two parts. The first, on invention, covered the topics, and the second, on judgment, presented a deliberately simplified version of the syllogism followed by an account of method as a means of ordering in the arts and sciences. No reference was made to such standard material as the categories, the square of opposition, conversion, demonstration and fallacies. On the other hand, the work is rich with quotations from the poetry and prose of classical authors, which must have strengthened the impression among students that logic was both easy and fun.

The book had a remarkable publishing history, but it is not clear how much impact it actually had on the university scene. In England, Ramus certainly enjoyed some popularity at Cambridge but was less well received at Oxford. Even in Germany, where 151 editions appeared, university teachers of logic soon found serious deficiencies in Ramus’ book, and in the 1590s a new school of textbook writers known as the Philippo-Ramists appeared in Germany. Their aim was to combine what was best in Ramus with what was best in the more Aristotelian work of Philipp Melanchthon. As a result, they tended to restore those parts of Aristotelian logic that Ramus had deliberately omitted, and the syllogism was once more presented as central to formal logic (see Logic in the 17th and 18th centuries §1).

6 Late scholastic textbooks

If England and Germany saw the production of slim textbooks exemplifying the marriage between humanism and a simplified Aristotelianism, Spain and Italy were the scene of a much more substantial textbook production. Two important texts, both recommended by the Jesuit *Ratio Studiorum* of 1599, and thus possibly studied by Descartes at La Flèche, were the *Introductio in dialecticam Aristotelis (Introduction to the Dialectic of Aristotle)* of Franciscus Toletus (§3) and the *Institutionum dialecticarum (Dialectical Instructions)* of Pedro da Fonseca (§2). Toletus’ book was first published in Rome in 1560, and the last of its eighteen editions appeared in Milan in 1621. Fonseca’s work was first published in Lisbon in 1564, and the last of its fifty-two editions appeared in Lyons in 1625. The works were fairly similar in content. The Organon is very much central but medieval material is used to supplement Aristotle in various places. Exponibles are discussed, albeit in a simplified form; some non-syllogistic consequences dealing with truth and modality are listed, and material about supposition and related doctrines is presented as an aid to understanding fallacies.

The most important English text of this type was Robert Sanderson’s *Logicae Artis Compendium* which appeared at Oxford in 1615 and was to remain a standard text there until well into the eighteenth century. This, too, contains a full account of strictly Aristotelian logic, together with brief discussions of the medieval doctrines of supposition, exponibles and consequences, and a full discussion of method as a way of ordering discourse.

7 The discussion of method

A particular feature of textbooks, especially in the second part of the sixteenth century, was the discussion of method. First, and most important, is the study of scientific method, which is particularly characteristic of Italian universities. These had always been distinguished from Northern European universities by their strong emphasis on law and medicine, combined with a relatively slight emphasis on theology. The faculties of arts at such places as Padua provided studies leading to a degree in arts and medicine, and as a result the main emphasis was placed on logic and natural philosophy, as propaedeutic to medicine. In the fifteenth century works stemming from Oxford and Paris on such topics as the intension and remission of forms were particularly important (see Natural philosophy, medieval §6), but after about 1520 these works fell into sudden oblivion. By the mid-sixteenth century the focus of attention was on the Greek commentators and on Averroes (see Ibn Rushd), especially his *Physics* commentary. The main Aristotelian text studied was the *Posterior Analytics*. From Cajetan of Thiene (Gaetano da Thiene) (1387-1465) to Nifo there was a gradual refinement of writings on demonstration and scientific method which culminated in the work of Jacopo Zabarella (§4). His discussions of the methods of resolution, composition, and the so-called *regressus* (a method for uniting resolution and composition) were summarized in many later textbooks, often in uneasy alliance with two other types of method.

A second notion of method presents it as a way of organizing discourse, a method fully discussed by Agricola (§2). Agricola showed how argumentative and expository passages from classical literature could be analysed, a method which brought the logical text very close to the new humanist curriculum of many institutions (see Humanism, Renaissance §7). Agricola's approach was picked up and further popularized by Melanchthon (§2).

A third type of method is that of Ramus (§3), which is particularly directed towards the presentation of a subject, and best known for its presentation through diagrammed dichotomies. This too could be and was adapted to the analysis of literary and biblical texts.

Logical atomism

The name 'logical atomism' refers to a network of theses about the parts and structure of the world and the means by which language represents the world. Wittgenstein, in his Tractatus Logico-Philosophicus, expounds a version of logical atomism developed by him around the time of the First World War, as does Russell in works published contemporaneously. It is no accident that their work on logical atomism shares a common surface description since it resulted from their mutual influence at Cambridge. The common theme is that the meaning of our sentences is rooted in a primitive relation between simple expressions and their simple worldly bearers, the logical atoms. In a logically perfect language, atomic sentences describe configurations of these atoms, and complex sentences are combinations of the atomic sentences. But sentences of ordinary language may have a misleading surface form which is revealed as such by analysis. The common theme masks considerable differences of doctrine. In particular, there are differences in the nature of logical atoms and in the arguments for the existence of these atoms.

1 Wittgenstein's logical atomism

Wittgenstein's logical atomism is expounded in his *Tractatus Logico-Philosophicus* (1921) in which he explores the structure of the world and the structure of any language fit to represent the world (see Wittgenstein, L. §5). The unit of sentential representation is the atomic sentence, and Wittgenstein claims that every sentence can be analysed into a combination of atomic sentences which describe atomic states of affairs. Each atomic sentence has exactly one of the two truth-values, true and false, and there are no necessarily true or necessarily false atomic sentences. If an atomic sentence is true, then the state of affairs it describes exists, the existent atomic state of affairs being called 'an atomic fact'. If an atomic sentence is false, then the state of affairs it describes does not exist (see Facts §1; Truth, correspondence theory of).

An atomic sentence is structurally isomorphic to the atomic state of affairs described. It consists of an arrangement of names, and these names have simple objects as their meanings. The atomic state of affairs described by the atomic sentence consists of the named objects arranged in a way which corresponds to the arrangement of the names in the sentence. The objects named in atomic sentences and featuring in atomic states of affairs are Wittgenstein's logical atoms.

The atomic sentences form a system which is fit to represent any possible world. A possible world is represented by an assignment of truth-values to the atomic sentences. Atomic sentences are independent in the sense that there are no logical relations between them which rule out certain assignments of truth-values to the atomic sentences. The actual world is completely described by the atomic sentences which are true and false in it. So the actual world is the totality of atomic facts, the existent states of affairs described by the true atomic sentences.

Atomic sentences form the basis for Wittgenstein's analysis of the sentences of ordinary language. Any sentence of ordinary language has a unique translation into a sentence which is a truth-functional combination of atomic sentences. This is the principle of extensionality. A complex sentence is a truth-functional combination of atomic sentences just in case the truth-value of the complex sentence is entirely determined by the truth-values of its constituent atomic sentences. The sentential connectives of the propositional calculus, such as 'Čamp;', yield truth-functional combinations of atomic sentences.

Some truth-functional combinations of atomic sentences yield sentences which are true no matter what truth-values are assigned to the constituent atomic sentences, and sentences which are false no matter what truth-values are assigned to the constituent atomic sentences. These are the tautologies (such as 'P or not-P') and the contradictions (such as 'P & not-P'), respectively. Wittgenstein claims that all necessary truths are tautologies and all necessary falsehoods are contradictions.

Sentences of ordinary language may appear to be atomic, but analysis can reveal them to be complex. The aim of analysis is thus to uncover the accurate representations of the world which lie behind the misleading surface forms of ordinary language. The unit of sentential representation is the atomic sentence, but an atomic sentence is itself compounded out of names which have simple objects as their meanings. Hence, the meaning of every sentence of our language is grounded in this primitive meaning relation holding between names and the simple objects which

they name. But the more familiar entities of ordinary discourse, such as tables and chairs, are complex. So a sentence about a complex entity is bound to be analysed as a combination of atomic sentences, these sentences describing the arrangements of the simple objects which are the parts of the complex entity. Here we have the idea of analysis as the decomposition of complex entities into arrangements of their simple parts.

Why should there be simple objects at all? Why can complex objects not divide for ever and ever into less complex parts? Wittgenstein argues a priori from the possibility of representation to the existence of his simple objects using a *reductio ad absurdum*. First, he assumes that there is an atomic sentence featuring an expression standing for a complex entity. Second, he brings in a background assumption that sense be determinate, that is, every sentence has exactly one of the two truth-values in any possible world. As an illustration, suppose that the sentence ‘the broom is to the left of the cupboard’ is an atomic sentence. It features the expression ‘the broom’ which stands for a complex entity. The broom exists only if its parts exist and are arranged in the right way. Consider a possible world in which the broom does not exist - our sentence is not true in this world. But neither can it be false. For the sentence is atomic and thus does not contain as part of its meaning a condition which determines that the sentence is false when the broom does not exist. But every sentence must be either true or false in any possible world. So an atomic sentence must contain only expressions which stand for simple objects.

This shows that simple objects must exist but does not tell us what they are like. It appears that Wittgenstein thought that this was not a logician’s job. Early interpreters of the *Tractatus*, taking their cue from Russell’s logical atomism and Wittgenstein’s examples, took the simples to be the units of perceptual experience, in other words sense-data. But the independence of atomic sentences precludes such an interpretation. ‘This sense-datum is red’ and ‘this (same) sense-datum is green’ would be atomic sentences but they cannot both be true.

Wittgenstein later came to think that his model of the relationship between language and the world was radically misconceived. His most immediate criticism was to reject the independence of atomic sentences, which he did by considering sentences featuring colour predicates. This was at the same time the denial that all necessary truths and falsehoods are tautologies and contradictions, respectively. For the necessary falsehood ‘this sense-datum is red and green’ is not a contradiction. In the first part of his *Philosophical Investigations* (1953) Wittgenstein mounts a sustained attack against the pivotal claims that the meaning of sentences is rooted in the relationship between name and bearer and that the sense of sentences is determinate. Thus the justification for the existence of logical atoms is overturned.

2 Russell’s logical atomism

Russell developed his logical atomism over two decades, beginning with ‘On Denoting’ (1905) and ending with ‘Logical Atomism’(1924) (see Russell, B. §11). During this time he continually revised his ideas. (This section sketches the version of logical atomism he expounds in the eight 1918 lectures entitled *The Philosophy of Logical Atomism*.) Russell had originally coined the phrase ‘logical atomism’ to distinguish his picture of the world as containing many separate things from the opposing picture advocated by the British Idealists, such as F.H. Bradley, according to whom the world is an indivisible whole. His logical atomism justifies his method of analysis, for this method aims to reduce ordinary sentences to complex combinations of atomic sentences, sentences which feature expressions standing for Russell’s many separate things.

Wittgenstein and Russell disagree about the structure of atomic sentences. For Russell, atomic sentences consist of simple symbols which divide into proper names and predicates. Simple symbols have simple things (Russell’s logical atoms) as their meanings. The mark of a simple symbol is that understanding it consists in being acquainted with its meaning. Russell held that one cannot be acquainted with an ordinary object such as a chair, but only with the perceptual experiences, the sense-data, one has in perceiving the chair, such as the visual experience of a brown rectangular patch and the tactile experience of a rough and hard surface. He also allowed that one can be acquainted with the meanings of predicates, properties and relations. So atomic sentences feature proper names standing for sense-data, and predicates standing for properties and relations of sense-data. For example, ‘this is red’ is an atomic sentence in which the proper name ‘this’ stands for a sense-datum and the predicate ‘…is red’ stands for a property ascribed to the sense-datum.

If an atomic sentence is true, it is made true by a corresponding atomic fact which contains the meanings of the simple symbols of the atomic sentence. For example, ‘This is red’ is made true by the fact consisting of the

sense-datum named by ‘this’ having the property redness. But Russell’s inventory of facts far exceeds Wittgenstein’s totality of atomic facts. He also has negative facts which make false sentences false. ‘This is red’ is made false by the negative fact that the sense-datum is not red. Further, Russell has general facts corresponding to true general sentences such as ‘All men are mortal’ and ‘Some man is mortal’.

Whereas Wittgenstein remains silent about the nature of his simple objects, Russell claims that his simples are sense-data and their properties and relations. This entails that Russell cannot hold that atomic sentences are independent, because two atomic sentences ascribing different colours to a given sense-datum cannot both be true. Russell is more specific about his simples because his argument for their existence turns on an epistemic condition, the principle of acquaintance. This principle holds that the understanding of any sentence consists in acquaintance with the meaning units from which the meaning of the whole sentence is compounded. The principle is satisfied by an atomic sentence because understanding such a sentence consists in acquaintance with the meanings of its simple symbols. A non-atomic sentence must be completely analysed into a sentence which consists entirely of simple symbols standing for objects with which we are acquainted. Analysis thus provides a route whereby the analysed sentence can be understood. The surface form of an ordinary sentence is not a reliable guide to the underlying meaning units which make up the meaning of the sentence. For example, ‘Socrates is snub-nosed’ seems to feature a proper name, ‘Socrates’, standing for a person. But Russell claims that the analysis of such a sentence reveals that ‘Socrates’ is not really a proper name but a descriptive phrase picking out a complicated logical construction from sense-data.

Sense-data and their properties and relations are thus not only the fundamental units of meaning, but also the ultimate constituents of reality. Socrates and his properties and relations are reduced to logical constructions from these ultimate constituents. This reduction has the epistemological advantage embodied in Ockham’s razor. By taking Socrates to be a logical construction from sense-data, one reduces the risk of error because beliefs about sense-data and constructions from sense-data are supposed to be more secure than beliefs about objects which stand behind the sense-data.

Russell’s logical atomism was well-received by the logical positivists who confused it with Wittgenstein’s logical atomism (see Logical positivism §3). They fixed on Russell’s reductionist programme for translating empirical sentences into sentences about sense-data. This programme is fraught with difficulties both of principle and detail. One chief difficulty, promoted by Wittgenstein in his *Philosophical Investigations*, is the alleged incoherence of a private language consisting of reports of a single person’s sense-data (see Private language argument).

Logical constants

A fundamental problem in the philosophy of logic is to characterize the concepts of 'logical consequence' and 'logical truth' in such a way as to explain what is semantically, metaphysically or epistemologically distinctive about them. One traditionally says that a sentence p is a logical consequence of a set S of sentences in a language L if and only if (1) the truth of the sentences of S in L guarantees the truth of p and (2) this guarantee is due to the 'logical form' of the sentences of S and the sentence p. A sentence is said to be logically true if its truth is guaranteed by its logical form (for example, '2 is even or 2 is not even'). There are three problems presented by this picture: to explicate the notion of logical form or structure; to explain how the logical forms of sentences give rise to the fact that the truth of certain sentences guarantees the truth of others; and to explain what such a guarantee consists in.

The logical form of a sentence may be exhibited by replacing nonlogical expressions with a schematic letter. Two sentences have the same logical form when they can be mapped onto the same schema using this procedure ('2 is even or 2 is not even' and '3 is prime or 3 is not prime' have the same logical form: 'p or not-p'). If a sentence is logically true then each sentence sharing its logical form is true. Any characterization of logical consequence, then, presupposes a conception of logical form, which in turn assumes a prior demarcation of the logical constants. Such a demarcation yields an answer to the first problem above; the goal is to generate the demarcation in such a way as to enable a solution of the remaining two.

Approaches to the characterization of logical constants and logical consequence are affected by developments in mathematical logic. One way of viewing logical constanthood is as a semantic property; a property that an expression possesses by virtue of the sort of contribution it makes to determining the truth conditions of sentences containing it. Another way is proof-theoretical: appealing to aspects of cognitive or operational role as the defining characteristics of logical expressions. Broadly, proof-theoretic accounts go naturally with the conception of logic as a theory of formal deductive inference; model-theoretic accounts complement a conception of logic as an instrument for the characterization of structure.

1 The Tarskian paradigm

Suppose we are given a theory of truth for a language *L*, a theory which explains how the truth-conditions of sentences of *L* are determined by their construction from the semantic properties of a set of primitive expressions. A semantic characterization of logical consequence and logical truth for *L* appeals to the idea of an 'interpretation' of *L*, that is, roughly, an assignment of semantic properties of the appropriate sort to the nonlogical (or 'lexical') primitive expressions of *L*, properties which, once assigned, determine a (unique) truth-value for each sentence in *L*. If *p* is a sentence and *S* a set of sentences of *L*, then *p* is said to be a logical consequence of *S* if *p* is true on each interpretation of *L* rendering every sentence of *S* true, and *p* is logically true if it is true on each interpretation of *L*.

The technical implementation of this idea for elementary logic goes back to Löwenheim (1915), but its full significance was appreciated only in the 1930s; it receives an important exposition in Tarski's 1936 paper 'Über den Begriff der logischen Folgerung' ('On the Concept of Logical Consequence'). Let *L* be an elementary first-order language. The logical constants of *L* are given by enumeration as the four connectives '$\neg$' (negation), 'Čamp;' (conjunction), '$\vee$' (disjunction), '$\rightarrow$' (material conditional) and the two quantifiers '$\forall$' (universal quantifier) and '$\exists$' (existential quantifier). In some cases, the identity symbol 'Čequals;' is also distinguished as a logical constant. The formulas of *L* arise in the following three ways: (1) by applying any primitive *n*-place predicate symbol *R* to *n* terms $t_1, \ldots, t_n$ to obtain a formula $R(t_1, \ldots, t_n)$; (2) by applying connectives to given formulas; and (3) where $x_0, x_1, \ldots$ is a fixed set of individual variables, by applying the quantifiers '$\forall$' and '$\exists$' to a variable x_n and formula p to give formulas $(\forall x_n)p$ and $(\exists x_n)p$. An interpretation of *L* consists, first, of a non-empty set *D*, its domain or universe; second, of an assignment of relations and functions of the appropriate type over *D* to the predicate and function symbols of *L*; and third, of an assignment of objects in *D* to each individual constant (or name) in *L*. If the identity predicate is treated as a logical constant, it is understood that the interpretation assigns to it the identity relation over *D*, that is, the set $\{\langle a, a\rangle : a \in D\}$.

If *J* is an interpretation of *L*, the meanings of the logical expressions determine, for each formula of *L*, when the

formula is true on *J* relative to an assignment of objects in *D* to the individual variables of *L*. Such an assignment may be represented by a sequence over *D*, that is, a function mapping the natural numbers $\{0, 1, 2, \ldots\}$ into *D*. A sequence *s* then expresses the assignment to each variable x_n of the object $s(n)$ from *D*. A formula which is true on *J* with respect to an assignment s is said to be 'satisfied' by *s* in *J*. The sequences which satisfy a given formula on *J* are determined by those which satisfy its component formulas (subformulas). Thus, for example, a sequence satisfies the conjunction of two formulas on *J* when it satisfies both conjuncts, and satisfies the negation of a formula when it fails to satisfy the formula. Finally, if $q = (\exists x_n)p$, a sequence *s* satisfies *q* on *J* if and only if there exists an assignment *s′* differing from *s* only in the value assigned to the variable x_n such that *s′* satisfies *p* in *J*. This expresses the idea that *q* should be true on an assignment if it is possible to vary the object assigned to the quantified variable in such a way as to make *p* true. An analogous clause may be given for the universal quantifier. The interpretation *J* is said to be a 'model' of a set *S* of formulas with respect to an assignment if each formula in the set is true in *J* with respect to that assignment; *S* is said to be 'consistent' if it has a model. Tarski then says that a formula *p* is a logical consequence of a set *S* of formulas if and only if for any interpretation *J* of *L* and assignment *s* in *J*, if *J* is a model of *S* with respect to *s*, then *p* is true in *J* with respect to *s*; equivalently, *p* is a logical consequence of *S* if the result of adding $\neg p$ to *S* is inconsistent. A formula is logically true if it is true in each interpretation of *L* with respect to each assignment; and two formulas are said to be logically equivalent when they are true in just the same interpretations relative to just the same assignments (see Tarski, A.; Model theory; Tarski's definition of truth).

2 Extensions of elementary logic

It is fair to say that the account of logical consequence and logical truth we have just sketched for elementary logic has set the standard for semantic accounts of these notions in other contexts. Typical of these are extensions of elementary logic that arise by treating additional quantifiers as logical constants.

A first-order quantifier *Q* may be regarded as describing a relation between a universe *D* (any non-empty set) and the subsets *E* of *D* such that the sentence $(Qx)(Ax)$ is true on an interpretation that assigns *E* to $A(x)$ over the universe *D*. Consider, for example, the quantifier symbol Q_0, read 'for infinitely many'. The sentence $(Q_0x)A(x)$ holds in an interpretation *J* if $A(x)$ holds in *J* relative to infinitely many values for the variable *x*. In effect, then, Q_0 describes the relation between a universe and its infinite subsets. Similarly, the quantifier Q_1 describes the relation between a universe and its uncountable subsets (if any), where a set is called 'countable' if it can be put into a one-to-one correspondence with a subset of the natural numbers. Q_0 and Q_1 are examples of 'generalized quantifiers' (see Quantifiers, generalized).

Elementary logic is characterized by three properties which are focal points of any evaluation of its extensions. The 'completeness theorem' for elementary logic states that if a formula *p* is a logical consequence of a set *S* of formulas in elementary logic, then *p* is in fact provable from *S* within the deductive systems for elementary logic usually considered. Combined with the soundness theorem, which states the converse property, this result has the effect of saying that the logical consequence relation for an elementary language can be represented syntactically: the consequences of any set are precisely the formulas that stand to that set in a syntactically characterized relation of deducibility. The 'compactness property' holds for a relation of logical consequence just in case a formula is a consequence of an infinite set *S* of formulas only if it is a consequence of some finite subset of *S*. Finally, the (downward) Löwenheim-Skolem theorem for elementary logic states that if a set of formulas has a model, then it has a model with a countable universe. The quantifiers Q_0 and Q_1 properly extend elementary logic in rather different ways: the consequence relation that arises by adding Q_0 to elementary logic has the Löwenheim-Skolem property but not the compactness or completeness properties; while the corresponding relation derived from Q_1 has both the completeness and compactness properties, but not the Löwenheim-Skolem property (see Keisler 1971). Other extensions of elementary logic have neither property. An example is second-order logic, which extends elementary logic by allowing quantification into predicate places (see Löwenheim-Skolem theorems and nonstandard models; Second-order logic, philosophical issues in).

3 Notions of invariance

In a model-theoretic definition of logical consequence, the logical constants are given simply by a list. The choice of one such list over another may seem, to some extent, ungrounded. Thus, Tarski wrote in 1936 that 'no objective

grounds are known to me which would permit us to draw a sharp boundary between the two groups of terms', that is, to solve the demarcation problem. However, in later years Tarski was led to a less sceptical attitude towards the demarcation problem (see Tarski 1966). The solution he suggested consisted of a very general condition - it is satisfied, in fact, by all of the generalized quantifiers usually considered - but one strong enough to exclude many of the expressions which are generally regarded as nonlogical. Let us formulate the requirement for the case of a quantifier symbol *Q* that applies to a formula $A(x)$ and variable *x* to yield a sentence $(Qx)(Ax)$. (The generalization of this constraint to other classes of expressions is straightforward and may be found in the literature - see McCarthy (1981: §3) and Sher (1991: ch. 4).) The meaning of *Q* must determine, for each chosen universe *D* and each interpretation of $A(x)$ over *D*, a truth-value for the sentence $(Qx)(Ax)$ over *D*. Now consider any one-to-one function mapping *D* on to an alternative universe D^*. Such a function fixes an interpretation for $A(x)$ over D^*, consisting precisely of the images under the function of the items in the given interpretation of $A(x)$ over *D*. The requirement is then that the two interpretations assign the same truth-value to $(Qx)(Ax)$. Such a function is said to constitute an 'isomorphism' of the one interpretation with the other; and so a succinct statement of the indicated condition is that the behaviour of a logical constant must be 'invariant under isomorphism of interpretations'. Tarski's suggestion is that the boundary between logical and nonlogical notions coincides with the boundary between the expressions which satisfy the present invariance condition and those which do not.

What is the significance of the invariance requirement? Interpretations are 'isomorphic' when they share the same structure, so the invariance condition says roughly that the semantic result of applying a logical constant should depend only on the structure of the interpretation of the expressions to which it is applied, independently of properties and relations specific to objects in any particular interpretation. This requirement may be used to confer a clear sense on one very traditional thesis about logical notions, namely that they are 'topic-neutral' concepts. Tarski noticed that this sort of topic-neutrality is related to a unifying idea behind certain generalizations of the notion of a 'geometry', an idea developed by the German mathematician Felix Klein (1872). Klein viewed a space *S* as being given by a set with a certain geometric structure. Consider a collection G of one-to-one transformations mapping this set onto itself. Geometric structures can in many cases be described by families of such transformations. For example, consider the collection of all transformations that can be defined in terms of rotations and linear motions (translations). Then the properties of (plane) Euclidean geometry are characterized by the fact that they are 'invariant under transformations of this type', in the sense that any such transformation maps a set *S* of points on to a set congruent to *S* and, conversely, any set congruent to *S* can be obtained from *S* by a transformation of this type. Similarly, topology, a generalized geometry, may be viewed as the study of those properties which are preserved by one-to-one transformations mapping a space 'continuously' (intuitively, without breaking or tearing it) onto itself. Tarski's idea was to use the limiting case of this situation to characterize logic: logic is the study of those properties of a 'space' (that is, a set or universe) which are preserved by *any* one-to-one transformation mapping that space onto itself or, more generally, onto some other set. The indicated invariance requirement for *Q* may be seen as the special case of Tarski's constraint where we focus on relations of a universe and its subsets of the sort described by quantifiers.

The invariance condition is generally regarded as necessary for logical status. The question we must now consider is whether it is also sufficient. One difficulty faced by an affirmative answer concerns the necessitation requirement: that it is not possible - in a strong, uniquely logical sense of 'possible' - that each member of a set of sentences is true and one of its logical consequences is false. The difficulty is that there appear to be expressions which are counted as logical by the invariance criterion which lead to consequence relations violating this requirement. For example, let *P* represent a fixed contingently false sentence of English, for example, 'The French Revolution failed'. Consider a quantifier symbol *Q* interpreted as follows: in any interpretation *J*, $(Qx)(Ax)$ holds in *J* if *P* and $A(x)$ holds for some member of *J*, or not-*P* and $A(x)$ fails for each member of *J*. Since *P* is in fact false, if *Q* were a logical constant then $(Qx)(Ax)$ would be logically equivalent to $(\forall x)\neg A(x)$. This is a violation of the necessitation requirement, since in a logically possible world in which *P* is true, $(Qx)(x = x)$ is true, but $(\forall x)\neg(x = x)$ is false.

However, it may be that the lesson to be learned from examples such as the one just considered is not that the invariance constraint fails to underwrite the necessitation requirement, but that the invariance requirement has been understood too narrowly (see Sher 1991; McCarthy 1987). The example would not arise if that requirement were

understood ‘rigidly’, that is, in such a way as to apply to the interpretation of *Q* ‘across all logically possible worlds’. For consider a world w_1 in which *P* is true containing the same objects as a world w_2 in which *P* is false. Then the transformation that associates each object with itself will map the interpretation of the formula x = x in w_1 on to its interpretation in w_2 (both are the whole universe), but the sentence $(Qx)(x=x)$ is true in w_1 and false in w_2, which shows that the invariance condition for *Q* breaks down if that condition is applied to the interpretation of *Q* across all logically possible worlds. Let us say that an expression satisfying this stronger invariance condition is ‘rigidly invariant’. The suggestion is then that rigid invariance be taken as the defining property of the logical constants. The problem created by this proposal lies in a threat of circularity: we would require a characterization of the notion of logical possibility, sufficient for a demarcation of the logically possible worlds, not dependent upon a prior demarcation of the logical constants.

4 Syntactic characterizations of logical notions

An alternative approach to the demarcation problem locates the distinctive feature of the logical constants in the role that they play in deductive arguments. On this view, a logical expression is one whose meaning can be characterized by a set of rules of inference of a certain sort. These rules may be formulated in different ways; for example, in terms of a sequent calculus, or a natural deduction system (see Natural deduction, tableau and sequent systems). Each formulation will incorporate in some way a distinction between rules that license the introduction of a logical expression in an inference (introduction rules), and those which describe the conditions under which it can be eliminated (elimination rules). Thus, for example, the introduction condition for conjunction may be given by the rule

$A, B/A \mathbin{\&} B,$

and its elimination conditions by the rules

$A \mathbin{\&} B/A, \quad A \mathbin{\&} B/B.$

A rule of the form

$X_1, \ldots, X_n/Z$

is to be read as an inference-licence, saying that if $X_1, \ldots, X_n$ have been inferred, then it is permissible to infer Z. The existential quantifier may be similarly characterized by the rules

$A(t)/(\exists x)A(x), \quad (\exists x)A(x)/A(c),$

where in the first rule t is any term and in the second c is a constant subject to the restriction that it not appear previously in the inference in question (the ‘non-occurrence restriction’). Analogous rules characterize the other notions of classical quantification theory.

The most straightforward reading of the syntactic view is that an expression counts as logical if and only if it is possible to write a set of introduction and elimination rules for it. Arthur Prior criticized this idea by means of a simple counterexample (1960). In the absence of substantive restrictions governing the interaction of introduction and elimination rules, it would seem that we could characterize a connective ‘tonk’ by means of the following pair of rules:

$A/A \text{ TONK } B, \quad A \text{ TONK } B/B,$

from which we obtain the schema A/B, licensing the inference of any sentence from any other, as a derived rule of inference! In order to avoid this sort of pathology, Belnap (1961) imposed the requirement that adding a logical constant to a given deductive system *S* by reference to a set of rules of inference result in a ‘conservative’ extension of *S*; one in which no formula in the notation of *S* is provable that is not already provable in *S*.

Even thus amended, however, the syntactic conception of what it is to be a logical constant would appear to be too liberal. Let *S* be a standard system of proof for elementary logic, and suppose that *P* represents a fixed nonlogical predicate. Consider the quantifier *Q* such that $(Qx)(Ax)$ holds in any interpretation *J* if and only if some object falling under *P* satisfies $A(x)$ in *J*. (Thus, for example, if *P* represents ‘…is a bird’, the quantificational expression *Q* means ‘For some bird…’.) Let S^+ result from *S* by adding the following introduction and elimination rules for *Q*:

$A(t), P(t)/(Qx)A(x) \quad (Qx)A(x)/A(c), P(c),$

where in the second rule *c* is an individual constant subject to the non-occurrence requirement. It may be shown that S^+ is a conservative extension of *S*, but the expression *Q* thus characterized is not a logical constant.

Belnap’s requirement may be seen as a by-product of a later viewpoint on syntactic characterizations of logical notions developed by Ian Hacking (1979). On this view, the fundamental rules of inference associated with the logical constants implicitly define their semantic interpretation. The three rules given above for conjunction determine its semantic interpretation in the following sense: there is precisely one truth table for ‘Čamp;’ with respect to which these rules are sound. The introduction and elimination rules for the existential quantifier can similarly be shown to characterize its semantic interpretation. It is clear that the indicated rules for *Q* do not thus characterize its semantic role, for its interpretation over any set varies with the interpretation assigned to *P*. Of course, to speak of a set of rules of inference as ‘characterizing’ the interpretation of a connective or a quantifier symbol presupposes that such an expression is to have an interpretation of the indicated (classical) sort; the justification of this assumption must be given in other terms. The idea is that in ascribing such an interpretation to an expression we look for the one - or *a* one - that makes the introduction and elimination rules associated with the expression truth-preserving; the expression counts as logical if over any universe there is only one such interpretation.

What is the relation between the semantic and syntactic solutions to the demarcation problem? One answer is that they correspond to two broad conceptions of the nature of logic (see Tharp 1975). On the first conception, logic is a theory of a certain type of deductive inference. On this view, what is distinctive about logical notions is their role in deductive inference, and logical consequence consists in a (perhaps idealized) type of deducibility. The syntactic view (on which, under very general conditions, a completeness result links a relation of logical consequence to the deductive system that characterizes the logical constants) provides a natural interpretation of this conception. An alternative conception, of more modern vintage, sees logic as an instrument for the characterization of structure. A logic (that is, a choice of logical constants) may be said to ‘characterize’ a structure if there is a set *S* of sentences in the logic such that any model of *S* exemplifies that structure. On this conception, the invariance criterion would seem to be very natural, for the behaviour of logical notions should be preserved under ‘structure-preserving’ transformations of any subject matter to which they are applied. From this point of view, there will be no particular premium on completeness, and the Löwenheim-Skolem property is an anomaly. Elementary logic is a paradigm of the first conception of logic and second-order logic typifies the second.

Logical form

Consider the following argument: All men are mortal; Socrates is a man; therefore, Socrates is mortal. Intuitively, what makes this a valid argument has nothing to do with Socrates, men or mortality. Rather, each sentence in the argument exhibits a certain 'logical form' and those forms, taken together, constitute a pattern that guarantees the truth of the conclusion given the truth of the premises. More generally, the logical form of a sentence of natural language is what determines both its logical properties and its logical relations to other sentences.

The logical form of a sentence of natural language is typically represented in a theory of logical form by a well-formed formula in a 'logically pure' language whose only meaningful symbols are expressions with fixed, distinctly logical meanings (for example, quantifiers). Thus, the logical forms of the sentences in the above argument would be represented in a theory based on pure predicate logic by the formulas '$\forall x(Fx \rightarrow Gx)$*', 'Fy' and 'Gy', respectively, where 'F' and 'G' are free predicate variables and 'y' a free individual variable. The argument's intuitive validity is then explained by the fact that the logical forms of the premises formally entail the logical form of the conclusion. The primary goal of a theory of logical form is to explain as broad a range of such intuitive logical phenomena as possible in terms of the logical forms that it assigns to sentences of natural language.*

1 Logical form in Aristotelian logic

Broadly speaking, the 'logical form' of a sentence of natural language is what determines both its logical properties and its logical relations to other sentences. Most notably, the logical form of a sentence *S* determines whether or not it is logically true, and the logical forms of the sentences in a set *K* together with the logical form of *S* jointly determine whether or not the latter is a logical consequence of the former.

Although particularly prominent in the twentieth century, due especially to the influence of Bertrand Russell, the idea of logical form can be traced back to Aristotle. In the so-called 'traditional logic' that stems from Aristotle's work in the *Prior Analytics*, the central form of argument is the 'syllogism', that is, an argument consisting of two premises and a conclusion. For example:

(1) Every whale is a mammal.
Some carnivore is a whale.
$\therefore$ Some carnivore is a mammal.

Aristotle was the first to recognize explicitly that the validity of a syllogism (that is, its conclusion being a logical consequence of its premises) is entirely independent of the common noun phrases, or 'terms', in its constituent sentences. Rather, each sentence in a valid syllogism such as (1) above exhibits a certain form and, taken together, those forms constitute a pattern that, of itself, guarantees the truth of the conclusion given the truth of the premises.

To capture this idea systematically, Aristotle first restricted his attention to syllogisms the constituent sentences of which exhibit any of four basic sentential forms, known traditionally as *A*, *E*, *I* and *O*, respectively: 'Every α is a β', 'No α is a β', 'Some α is a β' and 'Some α is not a β', where 'α' and 'β' represent the roles of the subject and predicate terms in such sentences. Thus, the first premise of (1) is of the sentential form *A*, and both the second premise and the conclusion are of the form *I*. These sentential forms alone, however, are not enough to characterize the pattern that (1) exhibits. A further logically relevant feature of (1) is the way in which the terms occur in its constituent sentences: 'carnivore', for instance, is the subject term of both the second premise and the conclusion but does not occur at all in the first premise. To capture this feature generally, Aristotle introduced schematic variables *F*, *G*, *H*,…. Call the result of replacing the terms in a sentence that exhibits one of the basic sentential forms with distinct schematic variables a 'schematic' form. The pattern exhibited by a given syllogism can then be represented by replacing its constituent sentences with schematic forms that preserve the arrangement of terms in the syllogism. For example, (1) exhibits the following pattern:

(2) Every *F* is a *G*.
Some *H* is an *F*.
Some *H* is a *G*.

By sole means of representations such as (2), Aristotle proved, for each possible syllogistic pattern, whether or not it is valid; that is, for Aristotle, whether or not it is impossible for the premises of any instance of the pattern to be true and the conclusion false. Thus, the schematic forms of its premises and conclusion (relative to a given choice of schematic variables) completely determine the validity or invalidity of each pattern. Aristotle's schematic forms are thus paradigms of logical forms.

The central goal of a theory of logical form is to explain the logical properties of (and relations between) the members of a broad class *K* of sentences of natural language in terms of the logical forms that the theory assigns to those sentences. With only four general types of logical form to choose from - the four basic sentential forms, the scope of Aristotle's account as it stands is far too limited to count as a fully fledged theory of logical form. However, a perusal of any modern text with a section on traditional logic yields a variety of techniques for translating sentences with entirely different grammatical forms into instances of Aristotle's four basic sentential forms. For example, a simple individual assertion such as

(3) Matthew is a politician

is obviously not an instance of any of the basic sentential forms, since it does not begin with one of the quantifiers 'Every', 'Some' and 'No'. But by introducing a term that picks out a class containing only Matthew, (3) can be translated into the intuitively equivalent, albeit somewhat stilted, sentence

(4) Every person identical to Matthew is a politician,

which exhibits the sentential form *A*. Again, a sentence such as

(5) Someone gave *The Brothers Karamazov* to Andrea,

which involves a transitive verb, can be put into the appropriate sentential form by replacing the verb with its nominal '-er' counterpart followed by the preposition 'of', to produce a term that picks out exactly the class of individuals to which the original predicate applies. (5) then gives way to

(6) Some person is a giver of *The Brothers Karamazov* to Andrea.

Supplemented by such techniques, Aristotle's logic has a considerably broader application, as a much larger class of sentences can be assigned logical forms than would initially appear to be the case. So supplemented, then, Aristotle's account is plausibly taken to be the first genuine theory of logical form (see Logic, ancient §§1-3).

2 A general characterization of logical form

Although differing considerably in content and detail, the basic components and characteristics of Aristotle's theory of logical form (in this somewhat anachronistic rendering) are essentially the same as in contemporary accounts deriving from Bertrand Russell. In this section, these components and characteristics are made explicit.

In general, the notion of logical form is always relative to a theory *T* of logical form which is directed towards some broad class *K* of sentences of natural language. Call *K* the 'target class' of the theory. The logical forms of the members of *K* are represented by formulas in a 'logically pure' canonical language; that is, a language that contains (perhaps in addition to punctuation) only variables and logical constants - expressions with fixed and, according to the theory, distinctly logical meanings (see Logical constants §1). For Aristotle, this is the language of schematic forms the logical constants of which are 'Every', 'Some', 'No', 'is a' and 'is not a'; and for Russell and his followers it is generally (some variant of) the language of *Principia Mathematica* (1910-13), with its now familiar quantifiers and propositional connectives.

The route from the sentences of the target class *K* to their logical forms according to *T* consists of two steps. First, and most important, is the translation of the members of *K* into an 'impure' hybrid language that consists of the canonical language supplemented by nonlogical constants: for Aristotle, ordinary terms such as 'carnivore' and also stilted terms such as 'person identical with Matthew'; for Russellians, individual constants such as 'Socrates' and *n*-place predicates such as 'mortal' (or perhaps abbreviations thereof such as '*s*' and '*M*'). These nonlogical constants carry the same meaning as their informal counterparts and are used to construct the hybrid language translations of the sentences in which those counterparts occur. The translation of a sentence of *K* into a hybrid

language is typically known as its ‘analysis’. (Sentences such as ‘Every boy danced with a girl’, which are logically ambiguous, should of course receive a distinct analysis for each possible reading.) The analysis of a sentence is a paraphrase of the sentence which displays its logical form overtly in its surface grammatical structure. Thus, (3) and (5) are translated as (4) and (6), respectively, while for the Russellian, (7), for example, is translated as (8):

(7) If every man is mortal and Socrates is a man, then Socrates is mortal.
(8) ($\forall y$(man(y) $\rightarrow$ mortal(y)) & man(Socrates)) $\rightarrow$ mortal(Socrates).

In the second step of the process, the logical forms for the sentences of *K* are derived simply by uniformly replacing all the nonlogical constants in the analyses of those sentences with variables of the appropriate type. So, for example (assuming a choice of replacement variables for the nonlogical constants), the sentences in (1) - which in this case are identical with their analyses - yield the logical forms in (2), and (8) likewise yields (9) as the logical form of (7):

(9) $(\forall y(Fy \rightarrow Gy)\ \&\ Fx) \rightarrow Gx.$

As noted, the primary goal of a theory *T* of logical form is to account for the logical properties of the sentences in its target class *K* in terms of their logical forms. This is accomplished by means of a logical theory for the canonical language of *T* in which formal correlates of the ordinary logical notions - logical truth, logical consequence and so on - are defined for the formulas of the language. The apparent logical properties of the members of *K* are then explained (or explained away) by virtue of the fact that the formal correlates of those properties hold (or fail to hold) among the logical forms of the members of *K*. Thus, once again, the intuitive validity of (1) is explained by the formal validity of (2). Similarly, for the Russellian, the intuitive logical truth of (7) is explained by the formal logical truth of (9) - typically understood as truth in any domain under any interpretation (relative to that domain) of the free variables ‘*F*’, ‘*G*’ and ‘*x*’, following the work of Tarski (1933; see Model theory). In either case, the actual meanings of the nonlogical expressions in the natural language sentences in question play no role in determining the logical properties of those sentences. Rather, as the theories demonstrate, the logical properties are determined by their logical forms alone.

3 Comparing theories of logical form

The central principle for comparing theories of logical form is the following:

CP *T′* is preferable (*prima facie*) to *T* if *T′* explains a greater range of logical behaviour than *T* without appeal to extralogical principles (or, ‘meaning postulates’).

To illustrate, intuitively (10) follows directly from (5):

(10) Someone gave something to Andrea.

And yet, in Aristotle’s theory, as noted, (5) must be analysed along the lines of (6) and (10) along the lines of (11):

(11) Some person is a giver of something to Andrea.

However, then the analyses (6) and (11) exhibit only the obviously invalid argument pattern

(12) Some *A* is a *B*.
Some *A* is a *C*.

To capture the original entailment, (12) must be treated as enthymematic: that is, there is a suppressed premise with the logical form ‘Every *B* is a *C*’, namely

(13) Every giver of *The Brothers Karamazov* to Andrea is a giver of something to Andrea.

Aristotle’s logic, therefore, explains the relation between (5) and (10) by introducing an extralogical principle linking the two predicate terms, in effect reducing it to an instance of the argument pattern (2).

By contrast, represented in predicate logic, the logical forms of (5) and (10) constitute the valid pattern

(14) $\exists x Hxyz$
$\exists y \exists x Hxyz$

Hence, that (10) is a consequence of (5) is explained on the basis of their logical forms alone, without appeal to any extralogical principles. So, *prima facie*, a theory based on predicate logic is preferable to Aristotle's theory.

The '*prima facie*' qualification in CP marks the influence of other factors besides extent of explanatory range that are relevant to an evaluation of competing theories of logical form. Two particularly influential principles can be observed in recent debates over the logical forms of one or another class of sentences: logical conservatism and ontological conservatism.

The shift from Aristotle to Russell exhibits a typical way in which one theory *T′* of logical form can broaden the explanatory range of another *T*; namely, by extending or otherwise subsuming the canonical language and logic of *T*. In such cases, the language of *T′* is able to provide logical forms for all sentences in the target class of *T*. In addition, the language of *T′* includes logical constants and classes of complex expressions not present in the language of *T* that enable *T′* to construct logical forms not available to *T*. Appropriate logical principles for its new forms then enable *T′* to explain logical phenomena that are left unexplained (without extralogical principles) in *T*, for example, (10)'s being a logical consequence of (5). The principle of logical conservatism stipulates that supplementation to a given canonical language should be kept to a minimum. More exactly, let *T* and *T′* be theories with roughly equal target classes and let *L* be a background logical theory (first-order logic, for example) that is common to both *T* and *T′*; then

LC *T′* is preferable (*prima facie*) to *T* if *T′* requires fewer extensions to *L* than *T*.

The increase in explanatory range of predicate logic, of course, is far too vast for LC to override CP in the choice between Aristotle and Russell. A better example is found in recent well-known work on the logical form of action sentences with adverbial modifiers. For example:

(15) April kissed Jonathan tenderly.

It is intuitively clear that (15) entails

(16) April kissed Jonathan.

Typical predicate logic analyses of these sentences represent 'kissed' and 'kissed tenderly' as distinct two-place predicates. The entailment is then explained by means of a meaning postulate to the effect that if *A* kisses *B* tenderly, then *A* kisses *B*. As with Aristotle's explanation of the relation between (5) and (10), then, in this explanation the apparent entailment is actually enthymematic. However, the entailment can be explained directly by treating an adverb such as 'tenderly' as an adverbial operator *t* that, when prefixed to an *n*-place predicate *F* (such as 'kissed'), yields a new *n*-place predicate [*tF*] ('tenderly kissed') (see Adverbs §1). The logic of these new constructions is then characterized generally by the principle that

(17) $[\alpha\Pi]x_1 \ldots x_n \rightarrow \Pi x_1 \ldots x_n$, for any adverbial operator α and *n*-place predicate Π.

The logical forms of (15) and (16), then, on this approach, are (18) and (19), respectively:

(18) $[tF]xy$
(19) *Fxy*

and so by the new logical principle (17), (16) follows from (15) directly in virtue of their logical forms.

Most philosophers would probably agree that this increase in explanatory range is significant enough to override LC and warrant the added apparatus. However, Davidson (1967) proposed a logically more conservative analysis which avoids the new apparatus. Specifically, for Davidson, the proper analysis of action sentences takes the structure of an action verb such as 'kissed' to involve an implicit parameter for an event. Thus, (15) is to be analysed as

(20) $\exists x$ (kissing-of(April, Jonathan, *x*) & tender(*x*))

(read, roughly, as ‘There is an event *x* such that *x* is a kissing of Jonathan by April and *x* is tender’), and (16) as

(21) $\exists x$ (kissing-of(April, Jonathan, *x*))

The entailment from (15) to (16) is then explained by standard logical principles governing conjunction and the existential quantifier, and the apparently hasty introduction of new constructions and unfamiliar logical principles is avoided. Since their explanatory ranges are the same, then, CP provides no support for the adverbial operator account over Davidson’s, and so, by LC, Davidson’s account is to be preferred (see Adverbs).

As Davidson’s account illustrates, however, conservatism with regard to logic is often accompanied by liberalism with regard to ontology - in this case, the postulation of events. The ‘ontological commitments’ of a theory *T* of logical form consist of the kinds of things that must exist if the analyses that *T* assigns to the sentences of its target class are to be meaningful (see Ontological commitment). The second principle - ontological conservatism - is that such commitments are to be kept to a minimum; that is, more exactly, where again *T* and *T′* have roughly equal target classes,

OC *T′* is preferable (*prima facie*) to *T* if *T′* has fewer ontological commitments than *T*.

Unlike LC, this principle favours the operator account of adverbial modification over Davidson’s more ontologically permissive account. The choice between the two thus turns on one’s preferred brand of conservatism.

LC tends to be overridden by CP when they conflict, as additional apparatus is usually viewed as a small price to pay for greater explanatory range. However, more is often at stake in conflicts between CP and OC, as theories of logical form that have great explanatory range often exact a high price in ontological commitment: possibilia (that is, possible but non-actual objects) are introduced to explain sentences involving modality (see Modal logic, philosophical issues in §§1-2), intensional entities to explain the logic of attitude verbs (see Propositional attitude statements §§1-2) and so on. One must either choose between the two or offer a competing account with the same explanatory range but fewer ontological commitments. Since Russell first formulated his theory of descriptions (see Descriptions) to counter what he saw as Meinong’s ontological excesses, the development of competing theories of logical form has been, and largely remains, the primary tool for metaphysical discovery and the central approach to metaphysical debate in the twentieth century (see Analytical philosophy).

McGuinness, London: Routledge, 1975.(A unique, highly influential work by Russell's most famous student in which a very interesting, somewhat eccentric notion of logical form plays a prominent role.)

Logical laws

There are at least three different kinds of answer to the question 'What is a logical law?' One establishes what it means for something to be a logical law. This answers the semantic question: What is the meaning of 'logical law'? The second explains what makes something a logical law. This answers the metaphysical question: What is the ground of logical law? The third tells you what the logical laws are. This answers the question: What is the extension of 'logical law'?

Even though logic is often seen as a complete science, the answers to all three questions are disputed. For example, there are at least three different conceptions of what it means for something to be a law of logic. Different conceptions account for logic in terms of necessity, truth in all models, and proof.

There are also different answers to the metaphysical question. If truth-preservation is central to logic, then the ground of logic depends on the metaphysics of truth. If logic is a matter of the meanings of terms, then the metaphysics of meaning is important for logic. Unfortunately, there is no widespread agreement on the metaphysics of meaning or truth.

Finally, there is no widespread agreement as to what the logical laws are. There are two general disputes here. First, it is not clear what notions count as logical. Does logic contain laws about identity, second-order quantification or modality? Second, given agreement on the scope of logic, there are still questions about the logical laws in that area. Intuitionists, quantum logicians, relevance and paraconsistent logicians each reject things taken as laws by others, even in the language of 'and', 'or' and 'not'.

1 The semantic question

When we claim that something is a logical law, what do we mean? Sometimes we use 'logical law' to mean 'theorem of a formal system'. Depending on taste, we might call theorems of first-order classical logic, or some other formal system, laws of logic. This is a derivative use of the phrase, akin to calling the claims of a particular scientific theory laws of nature. The propositions of a theory may be laws of nature, but only if the theory 'gets it right'. The theory must describe the world in the right way for its claims to be laws of nature. Similarly, theorems of a formal system are only logical laws if they 'get it right' in some appropriate way. The interest consists in elaborating what it means for a theory to 'get it right'. So, by 'logical law' we do not simply mean 'theorem in a particular formal system'.

Another non-answer to this question is that logical laws are the ways we cannot help but think. Anyone familiar with the history of logic in the twentieth century will be aware that almost any principle that some take to be a logical law, others reject as invalid. If a logical law is something to which no one can help but assent, nothing counts as a logical law. No purely psychological answer, in terms of 'laws of thought', will give us logical laws.

Now to a more plausible account. The goal in the study of logic is an account of deductively valid inferences: these are the logical laws. A deductively valid inference is one in which necessarily, if the premises are true, so is the conclusion. Laws of logic are those inferences that are necessarily truth-preserving. This conception goes back to Aristotle (see Logic, ancient §§1-3).

> A syllogism is a form of words in which when certain assumptions are made, something other than what has been assumed necessarily follows from the fact that the assumptions are such.
>
> (*Prior Analytics*: 24b18)

We are interested in necessarily truth-preserving inferences because given these, and given true premises from which to infer, we will never (and in fact, *can* never) deduce falsehood. Given our concern for finding truth and avoiding falsehood, it is easy to see why logical laws are interesting, on this picture. It is also clear how logic can be normative. Given that we have the goal of gaining truth and avoiding falsehood, we *ought* to deduce validly. (Which is not to say that we ought not reason in other ways as well.)

We have one answer to our semantic question: a logical law is a necessarily truth-preserving inference. However, many have found this answer unsatisfactory. The main reason for dissatisfaction with this account is the reliance upon the intensional notion of necessity. Some have sought to give an account of logical laws that has no recourse

to necessity, or to any other intensional notion.

There are two important analyses of logical consequence which, at least at first glance, avoid using the notion of necessity. One was given its canonical exposition by Tarski in his 1936 essay ‘Über den Begriff der logischen Folgerung’ (’On the Concept of Logical Consequence’), though it was prefigured by Bolzano in 1837. Tarski wrote ‘The sentence *X follows logically* from the sentences of the class *K* if and only if every model of the class *K* is also a model of the sentence *X* ([1936] 1956: 417; original emphasis).

There are no modal notions here, provided that there is an adequate non-modal explanation of what it is to be a model. There are a number of ways to do this, and there is no need for us to consider them in detail. Suffice to say that models are structures in which each of the non-logical constants in a language is given an interpretation in terms of the objects in the model, and the logical constants have a fixed interpretation in each model (see Logical constants §1; Model theory).

Model-theoretic notions of consequence do not, as they stand, make any appeal to modality. However, they do not give a modal-free account of necessary truth-preservation.

For example, the model-theoretic account needs a collection of logical terms. If *all* terms are logical, then the interpretation of each term is fixed, and there is only one model. This would make logical truth vacuous, as Tarski realized (1936). Now suppose that the terms ‘blue’ and ‘coloured’ are not counted as logical terms. The deduction ‘My car is blue; therefore my car is coloured’ fails to be valid on the model-theoretic account, because we can assign disjoint extensions to the predicates ‘blue’ and ‘coloured’. In contrast, the inference is necessarily truth-preserving. In this way, necessary truth-preservation and model-theoretic validity come apart. (For a detailed account of how the notions differ, see Etchemendy’s *The Concept of Logical Consequence* (1990).)

These two approaches to analysing logical validity differ quite sharply from a third account. According to the proof-theoretic account of validity, an argument is valid just when there is a proof of the conclusion from the premises. This approach is championed by Prawitz (1974) with many other constructivists, and Wagner (1987) (a non-constructivist) who sees this view in the work of Gottlob Frege. The proof-theoretic account grounds validity in the meanings of the logical constants. These meanings determine the validity of simple deductions (such as conjunction elimination: from $p \,\&\, q$ to derive *q*). An argument is valid if and only if there are simple deductions from the premises to the conclusion (see Proof Theory).

On this account, logical validity is analytic, and the epistemic function of logic (as a calculus for ideal justification) is obvious. As with model theory, a proof-theoretic account of validity depends on the choice of logical particles, and the rules that govern them.

The proof-theoretic account differs from the other two approaches. If validity is ultimately proof-theoretic, then the class of logical validities is recursively enumerable. If we can list the basic rules, we can list the valid deductions (provided that proofs are finite). Similarly, validity is compact (if *K* follows from *X*, then *K* must follow from some finite subset of *X*). Neither of these properties is essential to the other conceptions of logical validity.

Without doubt, each of these conceptions has a place in the study of logical law. It is harder to discern how they are to be related. My tentative proposal is this. Validity is a matter of necessary truth-preservation. Model-theoretic validity is important, because models can represent possibilities (however ontological commitment to possibilities is to be analysed). Sometimes, models do not represent real possibilities (as when the extension of ‘blue’ is not a subset of the extension of ‘coloured’) so, model-theoretic validity can differ from actual validity. Similarly, proof-theoretic validity can coincide with actual validity. Although analytic truth and necessary truth may not coincide in all cases, simple deductions involving logical particles are instances of necessary truth-preserving inferences. Perhaps these simple deductions will capture all of the necessary truth-preserving inferences in the language. In this case, the proof procedure is complete. On the other hand, the validities in the language may not be recursively enumerable, as in the case of second-order logic. In these cases, no recursive proof-theoretic account will capture all of the validities.

2 The metaphysical question

Even if we have decided what we mean when we call something a logical law, the issue of the *ground* of logical

law remains. If validity is necessary truth-preservation, an account has to be given of necessity and of truth. Similarly for the model-theoretic approach. If models are to bear any resemblance to the world, truth-in-a-model ought to have the same structure as truth *simpliciter*. In these cases, doctrines of truth are relevant to the outcome of logical theory. For example, intuitionists have claimed that, at least in the domain of mathematics, truth comes by way of construction or verification. This claim has resulted in disagreement about logical laws (see Intuitionistic logic and antirealism). The case is similar with quantum logic. Given a particular reading of the correspondence theory of truth (in which propositions correspond to subspaces of the Hilbert spaces of quantum physics), quantum logic seems to follow naturally (see Quantum logic). On the other hand, the correspondence, coherence or pragmatist theories of truth do not seem to dictate a particular theory of logic. Metaphysical doctrines of truth are relevant to an account of logic, but they need not determine that account.

Some take it that logical validity is independent of any particular account of truth, because logical laws are purely a matter of convention. Clearly convention has a large part to play in language, but it is much more than this to say that logical laws are simply true by convention. For example, it is clear that it is a matter of convention that 'snow is white or snow is not white' is used to express a truth (and hence, a logical truth). It is also a matter of convention that 'snow is white' refers to snow. In this case it would be very strange to say that the whiteness of snow is *purely* a matter of convention. Similarly, 'snow is white or snow is not white' is not true solely by convention, but also by the way the world is (see Necessary truth and convention).

Convention in logic is more at home in the view of logic as proof theory. Here, validity is a matter of the meanings of logical particles. Terms get meanings by convention. However, this does not exempt us from the difficult matters of semantics. Logic depends on the meanings of individual particles such as 'not'.

Is the meaning of 'not' a matter of its truth-functionality, and does this yield classical negation? Or is negation to be analysed inferentially, with intuitionists? The analysis of meaning undergirds the proof-theoretic account of validity. No account of logical validity exempts the practitioner from the difficult task of giving an account of the ground of logical law. This is essentially a matter of metaphysics and semantics.

3 The question of extension

Even given answers to the semantic and metaphysical questions, we are not at an end. We have yet to give an account of which inferences qualify as logical truths. Logicians have a ready supply of formal systems designed to do just this: there is a whole wealth of different formal systems designed to give an account of valid inference in different languages. These systems differ from each other in a number of ways. They can contain the truth-functional connectives, quantifiers for objects (both the standard existential and universal quantifiers, and perhaps more exotic quantifiers), quantifiers of higher order, the identity relation, modalities of various sorts, and so on. If validity is construed as necessary truth-preservation, there is no need to make a principled choice of logical constants, because any term may be relevant in determining validities. The only choice is a pragmatic one, of which laws are worth studying. The way is open for a logic of colour, a logic of perception sentences, a logic of action, or a logic of all three. These 'logics' will be partial accounts of validity, just as a theory of electromagnetism is a partial account of physical law.

On the other accounts of validity, a distinction must be made between logical and non-logical terms, in order for there to be a univocal sense of logical validity. This is not an easy task, because there are no principled criteria that something must satisfy in order for it to be a logical constant. People disagree over whether generalized quantifiers of objects (such as 'uncountably many') and second-order quantifiers ought to feature in logic (see Quantifiers, generalized; Second-order logic, philosophical issues in).

Second, formal systems may differ in terms of their results, even if they have the same language. For example, intuitionistic logic and classical logic disagree about double negation elimination (not-not-*p*; therefore *p*) provided that you take intuitionistic logic and classical logic to have the same vocabulary. There is a subtlety here. It is obvious that two different formal systems can be reconciled by treating them as modelling different things. Then intuitionistic logic and classical logic can be seen as not disagreeing, because they have different negations. Quine said as much when he claimed that changing a logic amounted to changing the subject (1970).

However, this is not the whole story. Classical logic and intuitionistic logic can disagree as to the validity of real arguments. Given a particular argument in natural language, an intuitionist and a classical logician may disagree

about its validity. If there is a fact of the matter as to whether the argument is valid, then classical logic and intuitionistic logic can be seen to disagree about this fact. The change of logic does not involve a change of subject when the subject (in this case, natural language arguments) is fixed in advance. Given a particular instance of the natural language ‘not’, classical logic and intuitionistic logic are different accounts of the valid arguments involving this fragment of natural language. The natural language particle is *prior* to its formalizations, which are intended to capture the meaning of the particle. These formalizations can capture the meaning well, or not well, and hence these formalizations can disagree.

With intuitionistic logic, the locus of disagreement is the conception of truth or, alternatively, the meanings of the logical particles. Given a verificationist or constructivist view of truth, you have a reason to be an intuitionist with regard to the standard logical particles. However, if you disagree with constructivism, and you do not analyse the meanings of logical terms in constructivist terms, you can use intuitionistic logic as a logic of necessary provability preservation. Disagreement about intuitionism can only be resolved by agreeing on theories of truth and meaning. The case is similar with quantum logic, as we saw before.

Disagreement becomes more subtle when we consider paraconsistency (permitting contradictions in some way to hold) and relevance. According to most logics, the argument from *p* & not-*p* to *q* is valid, but according to paraconsistent logics (including all logics of relevance - see Anderson and Belnap 1975; Anderson, Belnap and Dunn 1992), it is not. In this disagreement no doctrines of truth or meaning stand out as motivating the peculiar features of the logics. Instead, there seem to be two major reasons that proponents of these systems can have for analysing validity in this way.

The first is quite simple. If a contradiction were true, or even possibly true, it would be clear that the inference from *p* & not-*p* to *q* would be invalid. While many doubt the coherence of this supposition, enough work has been done in the field of paraconsistent logic to show that the approach is coherent (see Paraconsistent logic; Priest, Routley and Norman 1989).

If we admit the need to be able to deduce in inconsistent situations (whether they are epistemic situations, possible situations or actual situations), a logic without the inference from *p* & not-*p* to *q* is necessary. Note that this does not involve any particular doctrine about the nature of truth (correspondence, pragmatic or coherence), but simply the view that it is possible that a contradiction be true. Resolving such disagreements is a matter of examining the arguments for and against the truth of contradictions.

The second motivation for the view that the argument from *p* & not-*p* to *q* is invalid is quite different. On this view you need not hold that it is possible that a contradiction be true. Instead, you maintain that for an argument to be valid, and for a conditional to be true, its antecedent must be relevant to its consequent. If this is the case, then there may be a reason to reject the inference (see Relevance logic and entailment). Again, this disagreement is not about a particular doctrine of the nature of truth. Instead, it is a disagreement about the relationship between relevance on the one hand, and validity and conditionality on the other. Opponents can trade intuitions about the validity or otherwise of individual arguments, but this kind of discussion is rarely fruitful. A saner approach might go as follows: if the relevantist can develop a coherent theory of validity, which models our valid argument at least as well as can be done otherwise, and which, in addition, gives an account of phenomena that cannot be modelled otherwise, then, clearly, the relevantist position is viable and valuable. If it cannot, it will not succeed as a theory of validity.

In all of these considerations, we have seen that logic is quite similar to other sciences. The practitioners have some idea of what the subject matter is (valid inferences) but there is debate about its exact nature. The task is to model the subject matter, and there is no wide consensus about how this is to be done. However, as in other sciences, this does not mean that the study is not worthwhile, nor that it will not enrich our knowledge of the way things are.

Logical positivism

Logical positivism (logical empiricism, neo-positivism) originated in Austria and Germany in the 1920s. Inspired by late nineteenth- and early twentieth-century revolutions in logic, mathematics and mathematical physics, it aimed to create a similarly revolutionary scientific philosophy purged of the endless controversies of traditional metaphysics. Its most important representatives were members of the Vienna Circle who gathered around Moritz Schlick at the University of Vienna (including Rudolf Carnap, Herbert Feigl, Kurt Gödel, Hans Hahn, Karl Menger, Otto Neurath and Friedrich Waismann) and those of the Society for Empirical Philosophy who gathered around Hans Reichenbach at the University of Berlin (including Walter Dubislav, Kurt Grelling and Carl Hempel). Although not officially members of either group, the Austrian philosophers Ludwig Wittgenstein and Karl Popper were, at least for a time, closely associated with logical positivism.

The logical positivist movement reached its apogee in Europe in the years 1928-34, but the rise of National Socialism in 1933 marked the effective end of this phase. Thereafter, however, many of its most important representatives emigrated to the USA. Here logical positivism found a receptive audience among such pragmatically, empirically and logically minded American philosophers as Charles Morris, Ernest Nagel and W.V. Quine. Thus transplanted to the English-speaking world of 'analytic' philosophy it exerted a tremendous influence - particularly in philosophy of science and the application of logical and mathematical techniques to philosophical problems more generally. This influence began to wane around 1960, with the rise of a pragmatic form of naturalism due to Quine and a historical-sociological approach to the philosophy of science due mainly to Thomas Kuhn. Both of these later trends, however, developed in explicit reaction to the philosophy of logical positivism and thereby attest to its enduring significance.

1 Historical background

Immanuel Kant, in the positivists' eyes, had made a lasting contribution to scientific philosophy - particularly in his rejection of the possibility of supersensible metaphysical knowledge and his reorientation of theoretical philosophy around the two questions 'how is pure mathematics possible?' and 'how is pure natural science possible?' In answering these questions Kant developed his famous defence of synthetic a priori knowledge - knowledge independent of sensible experience yet nonetheless substantively applicable to the empirical world. For Kant, the mathematical physics of Newton paradigmatically exemplified such synthetic a priori knowledge through its reliance on Euclidean geometry and fundamental laws of motion such as the law of inertia. Kant's theory of a priori faculties of the mind - the faculty of pure intuition or sensibility and the faculty of pure understanding - was then intended to explain the origin of synthetic a priori knowledge and thus make philosophically comprehensible the possibility of Newtonian mathematical physics.

After the intervening dominance of post-Kantian idealism, a number of German-speaking philosophers renewed the call for a scientific, epistemological and non-metaphysical form of philosophy. But these Neo-Kantian philosophers also had to face an important new challenge to the Kantian synthetic a priori: the nineteenth-century development of non-Euclidean geometry by Gauss, Bolyai, Lobachevskii, Riemann and Klein (see Geometry, philosophical issues in §§1, 3). Although some Neo-Kantians attempted to defend the uniqueness and apriority of Euclidean geometry nonetheless, others - especially those of the Marburg School such as Paul Natorp and Ernst Cassirer - aimed to generalize the synthetic a priori beyond its particular embodiment in classical Euclidean-Newtonian mathematical physics (see Neo-Kantianism). This latter tendency was similar in important respects to ideas the logical positivists were to elaborate.

But the most important nineteenth-century predecessors of logical positivism were Hermann von Helmholtz, Ernst Mach and Henri Poincaré. Through their efforts to comprehend the radical changes sweeping through nineteenth-century science, these three thinkers initiated a new style of scientific philosophy later taken up and systematized by the positivists. The changes in question included the rise of non-Euclidean geometry, the formulation of the conservation of energy and general thermodynamics, and the beginnings of scientific physiology and psychology. Helmholtz made fundamental contributions to all three areas. He based geometry on the postulate of 'free mobility' of rigid bodies, and, since all classical geometries of constant curvature - negative, positive or zero (Euclidean) - satisfy this postulate, he opposed the Kantian commitment to the aprioricity of

geometry: whether space is Euclidean or non-Euclidean is an empirical question about the actual behaviour of rigid bodies. In physiology, Helmholtz articulated a general principle of psycho-physical correlation whereby our sensations correspond to - but are in no way pictures or images of - processes in the external physical world. These processes consist, in the end, of microscopic atoms interacting via central forces, and, on this basis, Helmholtz developed his famous interpretation of the conservation of energy.

Mach and Poincaré can be seen as reacting, in diverse ways, to Helmholtz. Mach attacked especially atomism and the idea of a psychophysical correlation between two incommensurable realms, and he advanced a programme for the unity of science based on immediately perceptible 'elements' or 'sensations'. The task of science consists solely in seeking correlations among such elements (as in phenomenological thermodynamics), and all dualistic and atomistic tendencies are to be purged as metaphysical via historico-critical analysis. This Machian empiricism exerted a decisive influence on the logical positivists. Poincaré, on the other hand, influenced the positivists primarily through his philosophy of geometry. He agreed with Helmholtz's emphasis on the free mobility of rigid bodies but disagreed with Helmholtz's empiricism. According to Poincaré, the idea of a rigid body is an idealization that cannot be straightforwardly instantiated in the physical world. By freely choosing one of the three classical geometries as, so to speak, a definition of rigidity, we then first make it possible to carry out empirical investigations with real physical bodies. Physical geometry is thus neither synthetic a priori nor empirical: it is 'conventional' (see Conventionalism).

2 Relativistic physics

Albert Einstein's special (1905) and general (1916) theories of relativity entered this volatile intellectual situation as a revelation (see Einstein, A.; General relativity, philosophical responses to; Relativity theory, philosophical significance of). And the relativistic revolution in physics directly stimulated Schlick, Reichenbach and Carnap to initiate a parallel revolution in scientific philosophy. All three thinkers agreed that relativity - especially through the general relativistic description of gravitation via a (four-dimensional) geometry of variable curvature - definitively refutes the Kantian idea that Euclidean geometry is synthetic a priori. Moreover, relativity arises from critical reflection on the empirical significance of spatiotemporal concepts in physics (in particular, the concept of simultaneity and the concept of motion) and thus demonstrates the fruitfulness of Mach's basic point of view. At the same time, however, through its use of sophisticated abstract mathematics, relativity also illustrates the limitations of Machian empiricism (according to which even mathematical concepts have an empirical origin). All three thinkers therefore attempted to formulate an intermediate position that would do justice to both Machian empiricism and the continued importance of a priori mathematical elements in physics. Poincaré's concept of convention came to play a central role.

Schlick, Reichenbach and Carnap first pursued rather different paths. Whereas Schlick emphasized from the outset that the Kantian synthetic a priori has no place at all in the new relativistic context, Reichenbach and Carnap initially attempted to salvage important aspects of Kantianism. Reichenbach began by distinguishing the idea of necessary and unrevisable truth from the idea of necessary presupposition of a given scientific conceptualization of nature. For Reichenbach, relativity refuted the former but embodied the latter. Kant was right that the necessary presuppositions of Newtonian physics included Euclidean geometry and the laws of motion. In moving to relativistic physics, however, these are replaced by fundamentally new presuppositions. We thus end up with a relativized version of the Kantian a priori (as constituting the presuppositions of a particular theory). Carnap, by contrast, began by distinguishing metrical from topological features of physical space. The latter are indeed synthetic a priori as Kant thought (they even depend on a kind of pure intuition), but the former - as general relativity has shown - essentially involve the behaviour of empirically given bodies. We thus end up with a weakening of the Kantian a priori (from metrical to topological features).

These early attempts to salvage aspects of the synthetic a priori did not survive, however. For Schlick's view that relativity is simply incompatible with Kant eventually won the day. Although the distinction between Poincaré's conventionalism and Helmholtzian empiricism was not entirely clear (and Reichenbach, in particular, preferred to associate his later viewpoint with Helmholtz rather than Poincaré), both Reichenbach and Carnap soon came to replace the Kantian notion of the a priori with Poincaré's concept of convention. Yet this form of conventionalism (unlike Poincaré's) was forged in the crucible of a revolutionary new physics and thus demonstrated the vitality and relevance of a new philosophy.

3 Logic and the foundations of mathematics

Whereas the positivists appealed to Poincaré's concept of convention (as realized, so they thought, in relativistic physics) to give a new answer to Kant's question concerning the possibility of pure natural science, they appealed to modern developments in logic and the foundations of mathematics to give a new answer to Kant's question concerning the possibility of pure mathematics. There were in fact two distinguishable sets of developments here. The formal point of view, typified by David Hilbert's logically rigorous axiomatization of geometry, freed geometry from any reference at all to intuitively spatial forms and instead portrayed its subject matter as consisting of any things whatever that satisfy the relevant axioms (see Geometry, philosophical issues in §2; Hilbert's programme and formalism). Geometry is rigorously and a priori true, not because it reflects the structure of an intuitively given space, but rather because it 'implicitly defines' its subject matter via purely logical - but otherwise entirely undetermined - formulas. Mathematical truth, on this view, is identified with logical consistency. The 'logicism' of Gottlob Frege and Bertrand Russell, by contrast, aimed to construct particular mathematical disciplines (especially arithmetic) within an all-embracing system of logic. On this view mathematical disciplines (like arithmetic) indeed have a definite subject matter about which they express truths: namely, the subject matter of logic itself (propositions, classes, and so on). As thus purely logical, however, such pure mathematical disciplines express merely analytic truths and are not synthetic a priori (see Logicism).

Hilbert's formal point of view was pursued especially by Schlick, who in a sense made the notion of implicit definition, together with the associated distinction between undetermined form and determinate (given) content, the centrepiece of his philosophy. The logicist point of view, by contrast, was pursued especially by Carnap, who studied with Frege and then was decisively influenced by Russell. Indeed, Carnap was inspired by Russell's conception of 'logic as the essence of philosophy' to reconceive philosophy itself on the model of the logicist construction of arithmetic. He began, in *Der logische Aufbau der Welt* (1928), by developing a 'rational reconstruction' of empirical knowledge - an epistemology - within the logical framework of Russell and Whitehead's *Principia Mathematica* (1910-13). By defining or 'constituting' all concepts of empirical science within this logic from a basis of subjective 'elementary experiences', Carnap's reconstruction was to show, among other things, that the dichotomy between empirical truth and analytic/definitional truth is indeed exhaustive.

Yet the logic of *Principia Mathematica* was afflicted with serious technical difficulties: the need for special existential axioms such as the axioms of infinity and choice. Partly in response to such difficulties, Ludwig Wittgenstein asserted in his *Tractatus Logico-Philosophicus* (1922) that logic has no subject matter after all: the propositions of logic are entirely tautological or empty of content (see Wittgenstein, L.J.J. §§3-7). Carnap eagerly embraced this idea, but he also attempted to adapt it to the new, post-*Principia* technical situation - which involved the articulation of the 'intuitionist' or 'constructivist' point of view by L.E.J. Brouwer and the development of meta-mathematics by Hilbert and Kurt Gödel (see Intuitionism §§2-3; Logic in the early 20th century §§6-9; Mathematics, foundations of). In *Logische Syntax der Sprache* (1934) Carnap formulated his mature theory of formal languages and put forward his famous 'Principle of Tolerance' - according to which logic has no business at all looking for true or 'correct' principles. The task of logic is rather to investigate the structure of any and all formal languages - 'the boundless ocean of unlimited possibilities' - so as to map out and explore their infinitely diverse logical structures. Indeed, the construction and logical investigation of such formal languages became, for Carnap, the new task of philosophy. The concept of analyticity thereby took on an even more important role. For this concept characterizes logical as opposed to empirical investigation and thus now expresses the distinctive character of philosophy itself.

4 The Vienna Circle

Otto Neurath, Hans Hahn, and the physicist Philipp Frank initiated a discussion group in Vienna, beginning in 1907, in which they considered a combination of Machian empiricism with Poincaré's new insights into the conventional character of physical geometry. Deeply impressed by Schlick's work on relativity theory, they arranged (apparently with Einstein's help) to bring Schlick to the University of Vienna in 1922 to take over the Chair in Philosophy of the Inductive Sciences previously held by Mach. What we now know as the Vienna Circle quickly took shape. Reichenbach, who had become acquainted with Carnap through their common interest in relativity, introduced him to Schlick in 1924. In 1925 Carnap lectured to the Circle in Vienna on his new 'constitutional theory of experience' and became assistant professor under Schlick in 1926. The Circle then

engaged in intensive discussions of Carnap's epistemology and Wittgenstein's *Tractatus*. Wittgenstein's view that all propositions are truth-functions of 'elementary propositions' was combined with Carnap 's constitution of scientific concepts from a basis of 'elementary experiences' so as to create a new, logically rigorous form of empiricism according to which all meaningful - scientific - propositions are reducible to propositions about immediately given experience. And this was articulated as the 'official' philosophy of the Vienna Circle in the famous manifesto *Wissenschaftliche Weltauffassung* in 1929.

Neurath was the driving force in thus turning the Vienna Circle into a public philosophical movement. Trained in economics and the social sciences, Neurath was extremely active politically as a scientific neo-Marxist. In particular, he took the community of natural scientists as the model for a rationally organized human society, and, on this basis, he advocated a reorganization of both intellectual and social life from which all non-rational, 'metaphysical' elements would be definitively purged. In this sense, Neurath saw the philosophical work of the Vienna Circle as a reflection of the wider movement for a *neue Sachlichkeit* then current in Weimar culture - as typified, for example, by the Dessau Bauhaus. As in the wider culture, this movement stood in philosophy for a rejection of individualism in favour of the cooperative, piecemeal, and 'technological' approach to problems exemplified in the sciences, and it was therefore particularly hostile to what was perceived as a return to the metaphysical system-building of post-Kantian idealism by influential German philosophers such as Martin Heidegger. Carnap was especially sympathetic to Neurath's broader philosophical-political vision and clearly expresses this vision in the Preface to the *Aufbau*. Schlick, by contrast, preferred a more individualistic model of philosophy and resisted the idea of a 'movement'.

This divergence between a 'left wing' and a 'right wing' of the Circle emerged in the sphere of epistemology in a debate over 'protocol-sentences' in the years 1930-4. At issue was the status of the basic propositions or protocols in which the results of scientific observation are recorded. It had initially appeared, in Carnap's constitutional system of the *Aufbau*, that such propositions must express private, subjective sense-experience. For Neurath, however, this view was inconsistent with the publicity and intersubjectivity required by science. He therefore advocated a more naturalistic conception of protocols as sentences accepted by the scientific community as recording the results of observation at a given time (see Naturalized philosophy of science). These sentences must thus be expressible within the public and 'physicalistic' language of unified science and hence, like all other sentences, are in principle revisable. Schlick was deeply shocked by Neurath's view - which he took to represent an abandonment of empiricism in favour of the coherence theory of truth (see Truth, coherence, theory of). Carnap attempted, in typical fashion, to mediate the dispute: at issue was simply a choice between two different languages in which to formulate or rationally reconstruct the results of unified science. Although Neurath's thoroughly intersubjective 'physicalistic' language (where, as Karl Popper emphasized especially, every sentence is revisable) was clearly preferable on pragmatic grounds, Carnap held that this choice - like every other choice of formal language - is in the end conventional (see Popper, K.R. §3). Empiricism, in Carnap's hands, is itself framed by conventional and hence non-empirical choices (see Vienna Circle).

5 Emigration, influence, aftermath

The rise of the Nazi regime set off a wholesale migration of logical positivists to the English-speaking world. Carnap, who had become professor at Prague in 1931, moved in 1936 to the University of Chicago. Reichenbach, who had fled to Istanbul in 1933, moved in 1938 to the University of California at Los Angeles. (After Reichenbach's death in 1953 Carnap took over his position at UCLA, beginning in 1954.) Neurath, after leaving Vienna for The Hague in 1934, fled to England in 1940 - where he worked in Oxford until his death in 1945. Friedrich Waismann fled for England as well, where he lectured at Oxford from 1939. Philip Frank emigrated to the USA (also from Prague) in 1938 and settled at Harvard in 1939. Karl Menger took up a position at Notre Dame in 1937, and Kurt Gödel became a member of the Institute for Advanced Study at Princeton in 1940. Herbert Feigl went first to the University of Iowa in 1933 and then to the University of Minnesota in 1940, where he founded the influential Minnesota Center for the Philosophy of Science in 1953. Carl Hempel joined Carnap at the University of Chicago in 1939 and, after teaching at Queens College and Yale, settled at Princeton in 1955. (Schlick was murdered by a deranged student at the University of Vienna in 1936.)

The growth of philosophy of science in the USA was decisively shaped by the work of Carnap, Reichenbach and Hempel. Reichenbach influenced especially the development of philosophy of physics through his work on

geometry, relativity and the direction of time (see Relativity theory, philosophical significance of §3). Hempel published extraordinarily influential papers on the logical analysis of explanation and confirmation and thereby furthered the ideal of scientific philosophy first articulated by Carnap (see Explanation; Confirmation theory). Carnap himself continued the construction of formal languages in which such concepts as testability, modality and probability could be rationally reconstructed or 'explicated' and thus contributed further to the same ideal. Indeed, Carnap's explication of concepts through the construction of formal languages influenced the English-speaking world of analytic philosophy far beyond the borders of philosophy of science. Developments in formal semantics and philosophy of language, in particular, rested on Carnap's initial work on modality (see Semantics §2).

The Carnapian ideal of explication is based on a sharp distinction between logical and empirical investigation, analytic and synthetic truth. In his *Logical Syntax of Language* (1934) Carnap had attempted a general explication of the concept of analyticity itself - a general formal method for distinguishing, within the context of any given formal language, the analytic from the synthetic sentences of that language. After accepting Alfred Tarski's semantical conception of truth in 1935, however, Carnap abandoned the approach of *Logical Syntax* and frankly admitted that (although explications for various particular languages could still be constructed) he now had no generally applicable explication of the concept of analyticity. After studying with Carnap in the early 1930s, W.V. Quine then exploited this situation to attack the concept of analyticity as such and, on this basis, to attack the Carnapian ideal of logical explication as well (see Quine, W.V. §§2, 4). Philosophy, for Quine, is itself a kind of empirical science - a branch of human psychology or 'naturalized epistemology' (see Naturalized epistemology). Moreover, at the same time that Quine was articulating this new philosophical vision, Thomas Kuhn published *The Structure of Scientific Revolutions* (1962) in the *International Encyclopedia of Unified Science* edited by Carnap and Charles Morris. Whereas Carnap had relegated the (conventional) choice of scientific language to the limbo of pragmatics, Kuhn concentrated on those factors - especially social factors - which, in a scientific revolution, determine precisely this kind of choice. These ideas, in harmony with Quine's more general naturalistic point of view, then led to historical and sociological approaches to the study of science and thus, in the end, to the decline of logical analyses of scientific language in the Carnapian style.

Logicism

The term 'logicism' refers to the doctrine that mathematics is a part of (deductive) logic. It is often said that Gottlob Frege and Bertrand Russell were the first proponents of such a view; this is inaccurate, in that Frege did not make such a claim for all of mathematics. On the other hand, Richard Dedekind deserves to be mentioned among those who first expressed the conviction that arithmetic *is a branch of logic.*

The logicist claim has two parts: that our knowledge of mathematical theorems is grounded fully in logical demonstrations from basic truths of logic; and that the concepts involved in such theorems, and the objects whose existence they imply, are of a purely logical nature. Thus Frege maintained that arithmetic requires no assumptions besides those of logic; that the concept of number is a concept of pure logic; and that numbers themselves are, as he put it, logical objects.

This view of mathematics would not have been possible without a profound transformation of logic that occurred in the late nineteenth century - most especially through the work of Frege. Before that time, actual mathematical reasoning could not be carried out under the recognized logical forms of argument: this circumstance lent considerable plausibility to Immanuel Kant's teaching that mathematical reasoning is not 'purely discursive', but relies upon 'constructions' grounded in intuition. The new logic, however, made it possible to represent standard mathematical reasoning in the form of purely logical derivations - as Frege, on the one hand, and Russell, in collaboration with Whitehead, on the other, undertook to show in detail.

It is now generally held that logicism has been undermined by two developments: first, the discovery that the principles assumed in Frege's major work are inconsistent, and the more or less unsatisfying character (or so it is claimed) of the systems devised to remedy this defect; second, the epoch-making discovery by Kurt Gödel that the 'logic' that would be required for derivability of all *mathematical truths can in principle not be 'formalized'. Whether these considerations 'refute' logicism will be considered further below.*

1 Preliminary discussion

Although the thesis that arithmetic is a part of logic was stated quite explicitly by Frege (1884, 1893, 1903) and by Russell (1903), it is surprisingly difficult to determine the exact content of this thesis; and, indeed, to determine whether it should be understood to mean the same thing to each of them. For the obvious question presents itself: exactly what are we to understand by 'logic'? How do we tell whether a certain basic assumption, or a certain basic concept, properly belongs to logic, or not? And, since an important part of the thesis is its epistemological aspect - the claim that mathematical knowledge is purely logical in nature - one would naturally expect an account of the grounding of our knowledge of logic. On the first of these questions - how to tell what belongs to logic - Frege has little to say (although he acknowledges the importance of the issue for his philosophy, and does provide a few pregnant suggestions); Russell has some lengthy considerations, which have proved not to be very satisfactory. On the second question, Frege and Russell appear to disagree sharply. Both regard the thesis as being in opposition to Kant; but whereas Frege, in denying that arithmetic is based upon any Kantian 'pure intuition' and maintaining that it is entirely grounded in logic, concludes that Kant was wrong to consider arithmetical propositions synthetic, and holds by contrast that, as propositions of logic, they are analytic (roughly speaking: known to be true by 'analysis' of their meanings alone), Russell denies the latter, and holds that logic itself is synthetic in character:

> Kant never doubted for a moment that the propositions of logic are analytic, whereas he rightly perceived that those of mathematics are synthetic. It has since appeared that logic is just as synthetic as all other kinds of truth; but this is a purely philosophical question, which I shall here pass by.
>
> (1903: 457)

Yet even here the issue is not so clearly drawn; for one must still ask whether Frege, in affirming that logic is analytic and not synthetic, and Russell, in affirming the opposite, understood the words 'analytic' and 'synthetic' in the same way - in particular, whether their opposite formulations might none the less have expressed the same opinions. The possibility is lent some weight by the fact that in certain late writings Frege refers to a 'logical source of knowledge' as a distinct knowledge-source (alongside 'sense perception' and 'the geometrical

source of knowledge') ([1924-5] 1979: 267, 278-9). Russell's view that logical truth is synthetic may be essentially identical with Frege's view that knowledge of such truth requires a 'knowledge-source'.

2 Connection with developments in arithmetic, algebra and analysis

The thesis that mathematics is a part of logic could not have been maintained before logic had undergone the deep transformation which took place in the late nineteenth century, most especially through the work of Frege. Before that time, actual mathematical reasoning could not be carried out under the recognized logical forms of argument. The new logic, however, made it possible to represent standard mathematical reasoning in the form of purely logical derivations. It is equally true that no such claim could have been made except for a deep transformation that had taken place in mathematics itself during the nineteenth century; and a brief consideration of this may help to shed some light on a plausible way to construe the logicist thesis.

From the time of Aristotle, it had been usual to regard mathematics as concerned with 'discrete' and 'continuous' quantity: whole numbers on the one hand; continuous magnitudes on the other. In the seventeenth and early eighteenth centuries it was generally supposed that our knowledge of mathematical truths was exclusively concerned with 'relations of ideas', and that - even if these ideas were obtained by some process of abstraction from empirical things' - this character explained how it is that the knowledge in question is certain and independent of experienced 'facts' (such a view was common, for instance, to the rationalist Leibniz and the empiricist Hume). Kant had presented arguments to subvert this position: he argued, rather convincingly, not just that logic (as it then existed) was insufficient to warrant the reasoning of mathematicians, but also that such reasoning demanded attention to more than 'ideas', or (rather) concepts - that a kind of mental visualization of the objects falling under mathematical concepts was an indispensable ingredient.

Among mathematicians - although within a fairly small circle - confidence in *either* the Kantian *or* the pre-Kantian traditional view of the nature of mathematical knowledge was disturbed by the development, in the early nineteenth century, of new forms of geometry: these seemed to show that neither mere consideration of 'relations of ideas' (that is, of such concepts as 'point', 'line', 'distance' and so on), nor the appeal to 'intuition', could decide the truth of propositions of geometry (see Geometry, philosophical issues in). At the same time, attempts were begun to work out new foundations for analysis - that is, the theory of the real (and complex) numbers, functions thereof, and limiting processes - that should be independent of any 'extrinsic' appeal to an 'intuition' of continuous magnitude. Again, in parallel (and partly in connection) with the preceding, systematic procedures were developed for the introduction of 'new objects' - or 'ideal objects' - in several branches of mathematics: for example, 'infinitely distant points' and 'points with imaginary coordinates' in geometry; real and imaginary numbers (alongside the rational numbers) in analysis; and, perhaps most decisively for our subject, 'ideal factors' of algebraic integers in the newly developing subject of algebraic number theory. In this last context in particular, Dedekind achieved fundamental new results with the help of concepts that involved the treatment of *classes* of (already introduced) objects as new objects ('modules', 'ideals', 'orders', 'number fields', among others) which could themselves be made subject both to general mathematical investigation and to actual calculation.

With all of this work in the background, Dedekind was led to examine the foundations of the theory of the whole numbers themselves; and he arrived at the conviction that this theory, together with algebra and analysis which are further derived from it, is 'a part of logic' - in saying which, he tells us, 'I mean to imply that I consider the number-concept entirely independent of the notions or intuitions of space and time, that I consider it *an immediate result from the laws of thought*' ([1888] 1901: 31; emphasis added). The way he develops his theory allows us to conclude that he regards both the concept of number and the theorems of arithmetic, as well as the concepts and theorems of the other mathematical theories he mentions, as resulting from certain fundamental abilities of the mind: the ability to form classes (his word is 'systems') of objects of thought (which themselves then have the status of such objects); to correlate or map such systems onto one another; and to 'create' new objects to 'represent' ones already present ('to relate things to things, to let a thing correspond to a thing, or to represent a thing by a thing'); and he tells us that without this ability, 'no thinking is possible'.

This version of the logicist thesis - namely, that mathematics (or that part of it which is claimed to belong to logic) requires no other source, either of its concepts or of its knowledge, than what is presupposed by all systematic thought - may be taken as applicable to the doctrines of all who have made that claim, whatever epistemological or

metaphysical differences may attach to their further elaboration of what those 'presuppositions of all thought' might be.

3 The logicist foundations of arithmetic

The fundamental problem for the logicist theory of the arithmetic of the ordinary whole numbers was to show how (1) the general concept of such numbers, (2) the individual numbers themselves, and (3) the modes of reasoning that suffice for the mathematical demonstrations of their properties, can all be derived from principles of logic. It will be convenient here to consider first the solution offered by Frege (1884), with which Russell's substantially coincides; a brief comparison with Dedekind's rather different approach will be made later.

Frege set about creating an entirely systematic and universally applicable formal system codifying all logical concepts and processes: his *Begriffsschrift*, or 'concept writing', which he characterized as 'a formula language…for pure thought' (1879). He therefore faced the task of making explicit, within the framework of such a formal system, how the cardinal numbers could be defined.

Now for Frege, as for Dedekind, a central logical role was played by a notion of 'class' - Dedekind's 'system', characterized by him in the following way:

> 'Such a system *S*…is completely determined when with respect to every thing it is determined whether it is an element of *S* or not. The system *S* is hence the same as the system *T*…when every element of *S* is also an element of *T*, and every element of *T* is also an element of *S*'
>
> ([1888] 1901: 45)

(Compare with 'extensionality' in Set theory, different systems of.) However, in Frege's opinion, such notions as that of a system or class, and that of a 'correspondence' ('a thing belongs to a thing') are 'not usual in logic and are not reduced [by Dedekind] to acknowledged logical notions' ([1893] 1964: 4). Frege therefore relies, for the *logical* ground of the notions of class and correspondence, upon the 'acknowledged' logical notions of a 'concept' (which when it is unary corresponds to a property, and when binary, ternary, …, to a two-place, three-place,…relation) and of the 'extension' of such a concept (in particular, the extension of a unary concept is a class). The existence of such an extension for every concept, satisfying the principle that two concepts have the same extension if and only if every object falling under either also falls under the other (see Dedekind's characterization of 'system' above), is a fundamental principle of the logic on which Frege bases arithmetic.

To avoid certain verbal complexities, we now follow Russell in formulating the arithmetic notions in terms of classes. Two classes *A*, *B* are said to be 'equinumerous' if, for some relation *R*: (1) for every element *x* of *A* there is an element *y* of *B* such that *x* has the relation *R* to *y*, but to no other element of *B*; and (2) for every element *y* of *B* there is an element *x* of *A* such that *x*, but no other element of *A*, has the relation *R* to *y*. One says that *R* is a one-to-one relation between *A* and *B*. 'Equinumerous', as just defined, is a binary relation that holds between certain classes. Being equinumerous with a given class *A* is, then, a property which holds of certain classes. In Frege's usage, the extension of this property [or concept] - and thus, the class of all such classes - is called 'the number of the class *A*'; thus we have succeeded, according to the premises of this whole procedure, in defining the individual numbers as 'objects', in purely logical terms. As to the general concept of number, that is now easy: '*n* is a number' means that there is some class *A* such that *n* is the number of the class *A*.

A most crucial step remains to be taken. We have defined the concept of number - allegedly at least - in purely logical terms; but this is too wide a concept to serve as the basis for ordinary arithmetic. Indeed, ordinary arithmetic has to do with the non-negative integers, and these, in the present context, are numbers of *finite* sets. But no such restriction appears in our definition of number: we have defined 'the number of the set *A*' for arbitrary sets - for example, for the set of all the points on a given line. At the same time - what at first will seem a quite unrelated issue - we have yet to show how all arithmetical reasoning can be carried out by purely logical argumentation concerning the number-concept.

The two issues have in fact a deep connection; and it is one of Frege's great accomplishments (also achieved independently by Dedekind) to have perceived the connection and found in it the simultaneous solution to both of them. A characteristic feature of reasoning in arithmetic is the 'argument from *n* to $n+1$', or the principle of mathematical induction:

If a certain property *P* holds of the number 0, and if whenever *P* holds of a number *n* it holds also of the number $n+1$, then *P* holds of all the whole numbers.

(Of course, to formulate this principle at all, one must have defined the process of adding 1 to a given number; but that is a detail, easily accomplished.) The chief problem for placing the argumentation of arithmetic on a 'purely logical' footing was to find a logical justification for this principle. But, speaking 'intuitively', it is clear that the principle in question cannot apply except to finite numbers (for the property of being finite holds of 0, and holds of $n+1$ whenever it holds of *n*; but of course holds only of finite numbers). This 'intuitive' argument can of course have no systematic standing so long as the notion of finite number has not been defined. Frege's idea, however, was to use this 'intuitive' insight as the basis for a purely logical definition of the concept of finite number:

A number *x* is said to be 'finite' if and only if *x* belongs to every class *C* such that: (1) 0 belongs to *C*; and (2) whenever a number *n* belongs to *C*, so does $n+1$.

With this definition, not only are the finite numbers singled out, but all the remaining concepts of traditional number theory can be introduced, and the reasoning of traditional number theory can be carried out within the framework of Frege's extended logic.

4 Extension to other mathematical domains

The extension of these results to the arithmetic of the rational, real and complex numbers offers no new fundamental difficulties, after the pioneering work that had already been done by mathematicians (see Numbers §7).

A difficulty does arise in the theory of functions: namely, the need - first brought to prominent notice by Zermelo (1904), who characterized it as a 'logical principle' - for what has come to be called the 'axiom of choice'; this says, in effect, that if *f* is a function defined on a domain *A*, such that, for each *x* in *A*, $f(x)$ is a non-empty set, then there is a function *g*, also defined on *A*, such that, for each *x* in *A*, $g(x)$ is an element of $f(x)$.

An interesting point arises when we come to geometry. Frege never extended the thesis of logicism to geometry; but, in a rather polemical exchange with Hilbert concerning the latter's path-breaking work on the foundations of geometry (see Frege 1980), Frege actually came near to formulating the point of view from which this extension can - and, indeed, so far as logicism is viable at all, *should* - be made: namely, one regards geometric theory - or, rather, *a* geometric theory (for there are infinitely many) - as concerned with a species of structure (of any one of which there may be many exemplars), characterized - indeed, defined - by the 'axioms' of that geometry; the theorems deduced from those axioms are then demonstrated 'by pure logic' to hold of any exemplar of the species so defined. That is the view maintained by Whitehead and Russell in the projected treatment of geometry in their major work, *Principia Mathematica* (1910-13). And it is the view that had already been expressed, in effect, by Dedekind and still earlier by Riemann (see Stein 1988: 244, 251-3). What is also noteworthy is that Dedekind, in contrast to Frege and to Russell and Whitehead, adopts the same point of view concerning even the system of the whole numbers: that is, he characterizes the *structure* a system must have to serve as that of the whole numbers, in explicit preference to identifying those numbers with any 'objects' specified in other than those structural terms.

5 The setbacks; a brief evaluation

The first of the setbacks for the logicist view was the discovery of a contradiction in Frege's logic (see Paradoxes of set and property §2), which arises from the assumption, already noted, that every concept has an extension - a very strong form of what has come, in the theory of sets, to be called a 'comprehension principle'. Frege himself was eventually led to abandon his logicist view of arithmetic, and to suggest instead that arithmetic is not only - as Kant thought - synthetic a priori, but is actually to be grounded in the 'geometric knowledge-source' ([1924-5] 1979: 276-80). Others, however - notably Russell ([1903] 1937: introduction), Ramsey (1925) and Carnap (1931) - felt no need to abandon the logicist thesis, but reconciled themselves to a modified view of logic, designed to circumvent the contradiction and still allow the essential modes of reasoning. Most celebrated among logicians as such a modified logic is Russell's 'theory of types'; but the axiomatic theory of sets, which has proved most serviceable as a medium for mathematics, could perfectly well also claim to be a form of 'logic' (see the characterization quoted from Zermelo, the pioneer of axiomatic set theory, in §4 above).

The second setback is more profound. Frege's own invention of a way of rendering logic purely formal made it possible to apply modes of mathematical reasoning to the formal linguistic structures of logical systems themselves. The undertaking of such application was a fundamental contribution of Hilbert. This process has further revolutionized our way of looking at logic itself. Among the most basic results of this examination are two theorems of Gödel (1930, 1931), one of which tells us that 'elementary logic' - or first-order logic - can be formulated so that every proposition that deserves to be considered logically true can be derived by 'purely formal', or 'mechanical', means (for example, these propositions can be generated by a computer program); whereas the other tells us that no such thing can be achieved for a system - whether a higher-order logic (of which the theory of types is an example), or a first-order axiomatized theory (of which set theory is an example) - that is strong enough to generate the theorems of elementary arithmetic.

With Gödel's theorems there should be mentioned a discovery that preceded them by several years: the Löwenheim-Skolem theorem (see Löwenheim 1915 and, for clearer and more adequate proofs, Skolem 1920, 1923). This theorem implies that any theory axiomatized in first-order logic that has an infinite model (domain that satisfies the axioms) has a countably infinite model (one whose domain can be placed in one-to-one correspondence with the natural numbers). In a very remarkable paper, Skolem (1923) invoked this theorem (and other considerations) to cast grave doubt on the view that set theory could be 'a satisfactory ultimate foundation for mathematics'. Indeed (restricting attention here to the implications of the Löwenheim- Skolem theorem), it is, for example, a fundamental proposition of classical analysis that the set of all the real numbers is uncountably infinite. The existence of a model for the allegedly foundational theory containing only countably many elements seems, then, prima facie to show that the foundational attempt has failed: that, in particular, the assertion within the theory that a certain set is uncountable has not captured what ought to be the genuine meaning of the term 'uncountable'. The issue is both deep and subtle; here, it must suffice to remark that both Gödel's theorems and the Löwenheim- Skolem theorem lead to the notion of nonstandard models - the theory of which has since become an important part of logic (see Löwenheim-Skolem theorems and nonstandard models).

These results may be summed up by saying that *there is not, and in principle cannot be, a 'completely formalized' logic within which all mathematically statable questions are correctly answerable*. Whether one chooses to call this a refutation of logicism, or an unexpected result about the 'uncompletable' nature of logic itself, the result is unquestionably a deep and interesting one simultaneously concerning mathematics and logic; and, for its discovery, a great debt is owed to those who advanced the thesis of logicism.

Logos

The noun logos *derives from the Greek verb* legein*, meaning 'to say' something significant.* Logos *developed a wide variety of senses, including 'description', 'theory' (sometimes as opposed to 'fact'), 'explanation', 'reason', 'reasoning power', 'principle', 'ratio', 'prose'.*

Logos *emerges as a philosophical term with Heraclitus (*c.*540-*c.*480* BC*), for whom it provided the link between rational discourse and the world's rational structure. It was freely used by Plato and Aristotle and especially by the Stoics, who interpreted the rational world order as immanent deity. Platonist philosophers gave pre-eminence to* nous*, the intuitive intellect expressed in* logos*. To Philo of Alexandria and subsequently to Christian theologians it meant 'the Word', a derivative divine power, at first seen as subordinate but eventually coordinated with the Father.*

1 Greek philosophy

Logos became an important term in almost all philosophical schools. It emerged about 700 BC as the accepted term for discourse at any length, though seldom if ever naming a single word; it displaced the older terms *epos* and *mythos*, which survived only with specialized meanings.

Heraclitus expounded a highly original philosophy in enigmatic phrases. *Logos* apparently means his own account of the world, which is 'common' but rarely grasped (frs 1, 2); it also suggests the everlasting cosmic order whose contrasting aspects or phases disclose an underlying unity (fr. 51). All phenomena spring from a basic element, fire, and return to it in regular 'measures' (*logoi*); earth exchanges with sea in the same proportion, *logos* (frs 30, 31, 90). This could suggest that changing phenomena can be known; but Heraclitus was seldom credited with this view.

The Sophists of the fifth century BC who *inter alia* taught the art of public speaking, naturally emphasized the power of *logos*, which Gorgias in his *Encomium of Helen* personifies as 'a great potentate who brings truly godlike things to pass' and Isocrates represents as the foundation of human culture.

Plato uses the term *logos* in almost all the senses mentioned above, though without giving it exclusive emphasis as compared with other cognate words (especially *dialektikē*, 'dialectic'); moreover, the general term *nous* for intellect, thought or intelligence is basic to his philosophy (see Nous); *logos*, and sometimes *dianoia*, 'thinking' (*Republic* 533d), stand for its expression. Both are contrasted with sense-experience (for example, *Republic* 509d) which Plato associates with instability and untruth; immunity from change is a precondition of real knowledge. In *Timaeus* 27-28 he contrasts unchanging being with change: 'the one is apprehended by thought (*noēsis*) with discourse (*logos*), being ever self-same; the other grasped by belief and unreasoned sensation'. Since mathematics expounds unchanging truths, Plato gave it an important place in his educational system.

He presents Socrates as initiating discussions which lead towards a 'true and certain and comprehensible *logos*' of ethical concepts and so promote right action, ignoring the body and its sensations as well as unsound *logoi* which lead to contradictions (*Phaedo* 90). Distrust of sense-experience is not always expressed; the *Seventh Letter* (344) states that knowledge calls for a combination of nomenclature, *logos* (definition), sensation and civilized discussion. The *Theaetetus* presents some attempts to define knowledge: it cannot be mere sensation, nor mere true belief, which might arise by accident; one must be able to give an account of it (*logon dounai*); but no satisfactory definition of *logos* is found. Discussion is necessary since written words can mislead (*Phaedrus* 275); its aim is to 'ignore all the senses [!] and press on through *logos* towards the essential reality of each thing' (*Republic* 532), its Idea or Form. Discussion (*dialektikē*) seeks a classification of all such Forms, showing their dependence on the Form of the Good, though this itself is an 'unpostulated' or absolute source, *anhypothetos archē* (*Republic* 510) (see Archē), 'beyond being in dignity and power' (509b).

Aristotle defines *logos* as a composite 'significant utterance', *phonēsemantikē* (*De Interpretatione* 4 16b26), but actually uses it in a wide variety of senses. It often deputizes for more specific terms, and thus traverses useful distinctions, for example, sentence/treatise, or proposition/syllogism. It often occurs in Aristotle's logical works, but the term 'logic' is a later coinage; Aristotle speaks of 'analytics'. His ethics prescribes following reason, or 'right reason' (*orthos logos*), sometimes conceived mathematically as a mean between two extremes. In his

metaphysics *logos* indicates, and sometimes equates with, the substance, form or essence of things (*ousia*, *eidos*, *to ti ēn einai*). Its relation to *nous*, pure intelligence, is left unexplained; but the intelligence moving the cosmos is always designated by *nous*, not *logos*. (See Aristotle §16.)

The Stoics held that only material things were fully real; but they were not, in the ordinary sense, materialists (see Stoicism §§3, 5). They held that the universe embodied a *logos* as its supreme directive principle. Natural objects, plants and animals have their own increasingly complex patterns of behaviour, culminating in the human reason, itself a lower analogue of the universal *logos*. This principle could thus be named in material terms as *pneuma* (spirit, breath; see Pneuma), in functional terms as *logos*, reason, and in valuational terms as *theos*, god. They did not, however, discard the common use of *logos* to denote purely human reason, or specialized forms of it ('argument', 'experience'); they accepted the common designation of animals as unreasoning, *aloga*.

Passions were commonly described as 'impulses contrary to *logos*' (see Stoicism §19); but were occasionally ascribed to, or identified with, 'a bad and licentious *logos*', and described as 'decisions', *kriseis*. But since *logos* could also mean 'the world order', conformity to *logos* could imply 'accepting the predetermined order of events', so that moral freedom was interpreted as resignation.

2 Christian theology: antecedents and developments

The Israelites came to believe that God's name, though revealed, should not be uttered; they used periphrases, for example, 'heaven', and ascribed divine action to intermediate agencies, including God's Word (*logos*) and his Wisdom (*sophia*). These are prominent in Philo of Alexandria, who held that the best Greek thought can be found, by appropriate exegesis, in the Jewish scriptures.

Philo echoes the 'dogmatic' Platonism reconstituted by Antiochus, with some Stoic elements, and Pythagorean ideas stemming probably from fellow-Alexandrian Eudorus (see Neo-Pythagoreanism; Platonism, Early and Middle §§4,8-9). He is our first extant source for the view that the Platonic Ideas are thoughts in God's mind. He describes the Logos as the 'Idea of Ideas' (*Migration* 103), the 'intelligible world' (*Creation* 24-), the 'divider' (*tomeus*) who arranged the pattern of Ideas for creation; indeed as 'a second God' (*Allegories* 1.32-), rightly honoured by those (Stoics?) unable to grasp the supreme reality. Stoic influence appears in his description of the Logos as 'fiery' (*Cherubim* 28) and 'physically pervasive' (*The Heir* 217). In *Immutable* 31 the Logos is God's elder son, the world his younger (compare the Platonist triad of God, the Ideas and matter?). Sophia is described in comparable terms; once only (*Flight* 109) she appears as 'mother' of the Logos, associated with God in a triadic divine family.

The New Testament appears as indifferent or even hostile to philosophy (*Colossians* 2:8). Exceptions are the hints of an 'argument from design' (*Acts* 17:22-29, *Romans* 1:20) and the prologue to the Fourth Gospel, apparently aimed at readers with philosophical interests, where the Logos appears as God's associate, a source of light or enlightenment, who in due course took human form. The title Logos suggests the Jewish theology of God's Word (*memra*) as developed in the biblical *Wisdom of Solomon* and Philo; it also expresses the Christian claim that Jesus is God's accredited representative and agent, appointed as his Son (see *Romans* 1:1-4, *Hebrews* 1-), the title which became dominant in the Gospel and the New Testament in general. The Christian Trinity of Father, Son and Spirit (2 *Corinthians* 13; 14, *c.* AD 55) - with the alternatives Logos and Sophia - can hardly derive from the very differently formulated triadic theology attributed to Moderatus (*c.*50-100), though later Christians could claim the support of philosophers such as Numenius. (Plotinus, who sees *nous* as the first derivative power, was little known to Christians before Augustine.)

Ignatius (*c.* AD 35-107) describes Jesus as God's Word (*logos*) 'proceeding from silence' (*Magnesians* 8.2). Justin Martyr (*c.*100-65) inaugurated a distinctive Logos-theology, which although retaining the Trinitarian confession emphasized the Logos, with philosophical echoes, as God's agent and interpreter at the expense of the Holy Spirit. Origen (*c.*185-*c.*254) was the most important exponent of this theology, which was superseded by the Council of Nicaea in 325.

Loisy, Alfred (1857-1940)

Loisy was a French biblical exegete who worked in the tradition of biblical criticism whose earlier members included D.F. Strauss and Ernest Renan. His critical views involved a sharp separation between the Jesus of history and the Christ of Catholic faith, and he came to regard the doctrine of the incarnation of God in Jesus Christ, a central Christian doctrine, as merely metaphorical and symbolic. He has been called the father of Catholic modernism.

Alfred Loisy was born in Ambrières, Marne, and was ordained a Catholic priest in 1879. He became Professor of Hebrew at the Catholic Institute in Paris in 1881, where he attended Ernest Renan's lectures from 1882 to 1885. He was made Professor of Biblical Exegesis in 1889, but was removed from his position in 1893 after publishing criticism of Catholic seminaries for not taking account of contemporary critical scholarship. From 1893 to 1899 he taught religion in Neuilly, and from 1901 to 1904 he was a lecturer in the École Pratique des Hautes Études in Paris. In 1909 he became Professor of the History of Religion in the Collège de France and also, after 1927, in the École des Hautes Études. Loisy came to describe his own views as pantheistic and positivistic, and was excommunicated in 1908.

Loisy's work was in the critical tradition of D.F. Strauss and Ernest Renan. In a series of works, he recorded and practised what the Church regarded as radical biblical and historical criticism. One example of this is his treatment of the fourth Gospel. (It is traditional in New Testament studies to refer to the Gospels of Matthew, Mark and Luke as the Synoptic Gospels, as distinct from that of John, the fourth Gospel.) In *Le Quatrième Évangile (The Fourth Gospel)* (1903), Loisy argued that the fourth Gospel is the coherent work of a single great theological genius, a symbolic description of Christian belief, a foundation stone of Christian truth, but not a trustworthy account of the life and teaching of Jesus Christ. The Synoptic Gospels, he held, are almost impersonal works which collect traditional reminiscences concerning Jesus, and have a greater historical value than the Gospel of John. More theologian than historian, still more an apologist or defender of the Christian faith, the author of the Gospel of John, according to Loisy, offers a brilliant history of Christianity since the resurrection of Jesus. But the Gospel does not deal with the times and events with which it ostensibly deals, namely what Jesus did and taught during his life and ministry. The author was unable to distinguish between what he received from tradition and what he found in the depths of his own imagination and conviction.

The fourth Gospel was intended, Loisy maintained, to support the legitimacy of Christianity in the context of contemporary Judaism. Its author manifests a supreme indifference to history, selecting from the traditional materials available what suits his purpose, and altering it as his purpose requires. That purpose is the construction of allegorical pictures that convey a wholly mystical and spiritual Christ, who is not subject to the conditions of historical human existence. The language used is figurative and ambiguous; it concerns a Christ who lives in the Church, and has scant connection with the Jesus who called disciples and was crucified. History belongs to the Synoptic Gospels, and the facts that they refer to receive theological and transcendental interpretation in the Gospel of John. But the difference in the worlds of thought occupied by the Synoptics and John is so great that the standard practice of weaving texts and themes from both sources into a single portrayal of the life and teaching of Jesus is undermined. This laid the foundation for a sharp distinction between the Jesus of history and the Christ of Catholic faith. Loisy saw in the author of the Gospel of John the first Christian mystic, for whom history is swallowed up in his mysticism.

Loisy's views, of course, were and are controversial, even setting aside the doctrinal implications that he drew from his critical work. Both his dismissal of the Gospel of John as a historical source and his treatment of that Gospel as theologically oriented in a manner different in kind from the other Gospels are challengeable.

Lombard, Peter (1095/1100-1160)

Peter Lombard's philosophical views are important given the formative role his Sententiae in IV libris distinctae (Four Books of Sentences) played in the education of university theologians in the high Middle Ages, many of whom were also philosophers. Peter staunchly opposes theologies, cosmologies and anthropologies of a Platonic or Neoplatonic type. While conversant with new trends in logic in his day, he is disinclined to treat theological issues as illustrations of the rules of formal logic or natural philosophy, preferring to view them from a metaphysical perspective. In his doctrine of God he deliberately eschews terminology associated with any one philosophical school. In his anthropology and sacramental theology he shows a marked preference for Aristotelianism. The hospitability of his theology to Aristotelianism and to a philosophical treatment of a range of theological questions made his Sentences elastic enough to accommodate the reception of Greco-Arabic thought and to serve as a pedagogical framework usable by philosophers of every persuasion during the succeeding three centuries.

Born in the Novara region of Italy, Peter left no traces on the historical record until he was noticed by Bernard of Clairvaux in the mid-1130s. With Bernard's advice and help, he went to France to study theology, first at the cathedral school at Rheims and then, in 1136, at Paris, probably under Hugh of St Victor. His earliest works were commentaries on the Psalms, written before 1138, and the Pauline epistles (first rescension 1139-41). He had become a recognized master by 1142. In 1145 Peter became a canon of Notre Dame, an unusual honour for a foreigner, teaching there until 1159 when he was elected bishop of Paris, a post he held until his death in 1160. His major work, the *Sententiae in IV libris distinctae (Four Books of Sentences)*, sums up his systematic theology. The final version of this work was completed in 1155-7.

For Peter, not all branches or schools of philosophy are equally pertinent to theology. He is uninterested in natural philosophy and says less about it than do the patristic authorities on whom he relies for his account of creation. He is familiar with the logicians' debates over universals. Without taking a personal stand on the priority or posteriority of universals to concepts standing for individuals, he refers to them in glossing 'all creation' (Romans 8: 19), which, he states, is a universal collecting all aspects of the human nature that is to be saved. Peter applies the contemporary nominalist view of the unitary signification of nouns and verbs and their consignification in oblique cases or past and future tenses, using this principle against Peter Abelard's argument that God could do otherwise or better than he does, in a defence of divine omniscience and omnipotence that contributes to the development of the distinction between God's absolute and ordained power (see Abelard, P.; Nominalism; Omnipotence).

Peter rejects any kind of emanationist, exemplarist or immanentalist understanding of God and his relationship to creation, as well as the equation made in some quarters during his time of the Platonic One, Nous and World Soul with the Trinity (see Neoplatonism). In glossing Romans 1: 20, he agrees with Marius Victorinus that the Neoplatonic triad of being, life and thought is apposite to the Trinity but his appreciation of the Platonic tradition stops there. Sometimes he favours a philosophical vocabulary neutral enough to shoulder its theological duties, unconstrained by the denotations which particular schools impose on key terms. At other points he opts for Aristotelianism. Opposing the Platonic notion of the human being as a soul using a body, he joins the Aristotelians in defining it as an integral union of body and soul. This principle undergirds his treatment of the creation of mankind, the fall and its consequences, Christ's human nature, the redemption, ethics and the sacraments. While he accents inner intentionality in ethics, he thinks that good intentions should be expressed in appropriate external actions, and while he holds that it is consent that makes a marriage, he regards the physical as well as the spiritual union of spouses as sacramental. He calls the present consent of spouses the efficient cause of marriage, and the ends of marriage (fidelity, lifelong commitment and offspring) its final cause. He applies 'substance' and 'accidents' in their Aristotelian sense to the change in the eucharistic elements at the time of consecration.

In other areas, Peter's use of Aristotelianism is muted by his felt need for a more neutral lexicon or because he wants to emphasize something else. He offers four proofs for God's existence, including Aristotle's argument from motion to a prime mover. His other proofs move from physical to metaphysical arguments in accenting the idea that the deity is the ground of being of the creation, rather than the idea that he is the cause of effects in the

phenomenal world (see God, arguments for the existence of). In treating the deity, Peter prefers a generic definition of 'substance' as referring simply to an entity's basic nature, because the Aristotelian understanding of 'substance' as referring to composite created beings is inapposite to God. Similarly, he rejects the Aristotelian definition of 'relation' as an accident when he discusses the mutual relations that name the persons of the Trinity. In another case, his doctrine of conscience as the spark of reason not extinguished even in the worst of sinners, Peter draws on an idea ultimately Stoic in provenance which he is the first medieval thinker to revive (see Stoicism).

More generally, Peter's acknowledgement of natural reason as a real epistemic state and his positive use of it in theology in opposition to Neoplatonic negative theology, his resolutely metaphysical approach to the deity and to the unmanifested Trinity as the supreme objects of knowledge that reason can address, and his interest in human nature as such, before the fall, open up zones for philosophical reflection which later scholastics could and did develop, whatever their philosophical proclivities. While issuing Aristotelians a warning concerning the appositeness of 'substance' and 'relation' to the divine nature, he provides notable support for that school. At the same time, he throws down the gauntlet to defenders of a more thoroughgoing Platonism.

Lonergan, Bernard Joseph Francis (1904-84)

The Canadian philosopher and theologian Bernard Lonergan approached the problems of philosophy by inviting his readers to attend to the mental acts in which they engage when they come to know anything. He claimed that these acts are of three fundamental kinds: 'experience' of the data of sensation, feeling or mental activity; 'understanding' possible explanations of that experience; and 'judgment' that one such explanation is in each case certainly or probably so. Denial that we engage in these three types of mental activity is actually self-destructive, since we have to engage in them in the very act of justifying such denial. In getting to grips with what it is to come to know, we also gain a vital clue as to the overall nature of the world which is to be known; and light is thrown on the relation between the natural and the human sciences, and on the questions of ethics and religion.

1 The nature of knowledge

Bernard Joseph Francis Lonergan was born in 1904, in Buckingham, Quebec. He entered the Jesuit Order in 1922, and studied at Heythrop College, England, and the Gregorian University in Rome. After some years as professor of theology at Jesuit seminaries in Montreal and Toronto, he was appointed to the faculty of the Gregorian University in 1953. In 1965 he returned to Canada, after a serious illness; later he taught at Harvard Divinity School, and finally at Boston College.

'Thoroughly understand what it is to understand, and not only will you understand the broad lines of all there is to be understood but you will possess a fixed base, an invariant pattern, opening upon all further developments of understanding' (Lonergan 1957: xxviii, 748). The main object of Lonergan's most substantial philosophical book, *Insight: A Study of Human Understanding*, is to get readers to take possession of their own rational self-consciousness; once this is done the philosophy which he calls 'critical realism' will show itself to be the only one which does justice both to human knowledge and to the world which is to be known by it. The true judgments of which human knowledge consists are to be arrived at by putting two kinds of question to the data of experience. I may inquire with respect to any phenomenon what it may be, or why it may occur; and having thought of an answer, I may ask another sort of question with respect to that, 'Is it so or not so?' The first kind of question, which culminates in an act of understanding or 'insight', Lonergan terms 'a question for intelligence'; the second, which issues in a judgment that something is the case or not the case, 'a question for reflection'. Questions for reflection, as opposed to those for intelligence, may properly be answered 'Yes' or 'No'. 'What sort of a rose is that?', or 'What is the cause of the unpleasant smell in this room?', cannot be answered in such a way; but 'Is it a rugosa?', or 'Is it the fish we threw into the garbage yesterday?', may certainly be so. Examples of the two kinds of question, and of the answers which may be given to them, are readily to be found in the most ordinary circumstances of life, as well as in the further reaches of theoretical science and scholarship. After *Insight*, Lonergan refers to the 'transcendental precepts' - 'be attentive, be intelligent, be reasonable' - which correspond respectively to experience, understanding and judgment; and claims that these precepts are relevant to the acquisition of knowledge of every kind.

It might be asked whether the claim that we perform such acts is not mere 'mentalism' or folk psychology, destined to disappear before the march of science. The answer is, that I cannot deny that I am at least to some extent really attentive, intelligent and reasonable, without thereby disqualifying myself from saying anything at all which is worth taking seriously. I can hardly argue soundly for a conclusion which implies that I am incapable of soundly arguing for a conclusion. And all such argument is a matter of being attentive, intelligent and reasonable - in other words, of attending to relevant evidence in experience, of envisaging possibilities which may account for that experience, and of affirming with more or less certainty the possibility which does seem best to account for it. Lonergan refers to the method underlying his philosophy as 'generalized empirical method', since it is based on our awareness not only of our sense-experience and feeling, but also of the mental acts (of questioning, hypothesizing, marshalling evidence, judging and so on) which we apply to these.

2 Science and metaphysics

With the advance of the sciences, it has become more and more clear that the possibilities which may be envisaged to explain what is observable are not themselves couched in terms of what is observable. Mass, valency and

electrical charge are not direct objects of sight or hearing; but they have been intelligently conceived and reasonably affirmed as constitutive of the best available explanation of a huge range of observable phenomena. 'Experiential conjugates' are properties of things in relation to our senses. 'Pure conjugates', as progressively discovered by scientific inquiry, are properties of things as related to one another. The moral, that knowledge can reach beyond experience, is also applicable to the notorious problem of other minds. Though I cannot have experience of your thoughts and feelings, I can certainly conceive that you may be thinking and feeling in a certain way, and verify the judgment that you are actually doing so on the evidence of my experience.

Does scientific realism commit one to determinism? (see Determinism and indeterminism; Scientific realism and antirealism). Modern physics seems to demand statistical laws to explain such phenomena as radioactive decay; there appears to be no adequate reason to suppose that these laws are a mere cloak for ignorance of underlying classical laws. The application within the universe of statistical as well as classical laws is to be grasped by what is called an 'inverse insight' to the effect that a whole familiar body of assumptions and strategy of questioning are wrong. (It is by inverse insight that one grasps that the square root of two cannot be the quotient of two whole numbers, however large, that one might have expected; or the crucial point of the special theory of relativity, that the common-sense notion of absolute rest is without application (see Relativity theory, philosophical significance of).) The world-order turns out to be constituted by 'schemes of recurrence' each characterized by a set of classical laws, and each with certain probabilities of emergence and of survival which are determined by statistical laws. These schemes of recurrence form a hierarchy corresponding to the different sciences (physics, chemistry, biology, sensitive psychology and so on).

Metaphysics, on Lonergan's account, is to be based on the theory of knowledge; the nature and structure of knowing determines the overall nature and structure of what is to be known. Reality is not the object of naïve extroverted consciousness, as we seem biased towards believing; it is nothing other than what is to be known so far as we exercise our attentiveness, intelligence and reasonableness to the full. 'Positions' in epistemology, metaphysics, ethics and so on, which are consistent with being intelligently conceived and reasonably affirmed, are to be distinguished from 'counter-positions', which are not so. Behaviourism in psychology is a fair example of a counter-position; since it follows inevitably from it that human beings, including behaviourists, never believe what they do because it is intelligent and reasonable for them to do so. Erroneous metaphysical doctrines are due largely to mistaking one part of the business of coming to know for the whole. Empiricism is 'a bundle of blunders', based on the fundamental error that 'what is obvious in knowing', that is, experience, 'is what knowing obviously is' (see Empiricism). Idealism rightly attends to the creative acts of intelligence which are essential in knowing; but does not take sufficient account of the fact that hypotheses concocted by intelligence may be verified or otherwise as obtaining in the actual world (see Idealism). The 'critical realism' which is for Lonergan the correct metaphysical stance takes account of the fact that knowledge is to be had in judgments as to what is so, in which experience and understanding both play their part. While taking full account of the 'turn to the subject' characteristic of philosophy since Descartes, critical realism reaffirms central elements in the philosophies of Aristotle and Aquinas.

3 Human science, ethics and religion

While the methods of the human sciences cannot be reduced to those of the natural sciences, it should not be inferred that a kind of divination is necessary to grasp the meanings implicit in human speech and action. In getting to know what Isaiah was about in propounding his oracles, or Churchill in pursuing his foreign policy, just as in the case of inquiries into the carbon cycle or the drift of the continents, I have to be attentive, intelligent and reasonable; the difference is that in the case of what is studied by the human sciences, the object as well as the subject of inquiry is to be understood as applying, at least to some extent, the same mental capacities. To envisage a fully 'scientific' account of human beings which would dispense with such 'primitive' and 'mentalistic' explanation is self-destructive for the reasons already given. All normally endowed human beings have experience, understand and judge; but it is one thing to do so, another to attend to the fact that one does so, another still to work out the consequences in an adequate philosophy. Throughout most of history, human worldviews have been dominated by myth, where thought on issues not immediately affected by practice is directed by emotion-laden images rather than by rational self-consciousness.

Value judgments, like (other) judgments of fact, may be due to more or less attentiveness, intelligence and

reasonableness; they have to be distinguished sharply from direct response to experienced inclination or aversion. I may want a good breakfast, and act accordingly; but I may also conceive and work for an economic order where as many people as possible get a good breakfast. Of course, it is one thing to make a value judgment, another thing to act in accordance with it. To complete our account of the transition from knowing what is true to knowing and doing what is good, a fourth kind of mental act, that of ‘decision’, has to be invoked; and a corresponding fourth ‘transcendental precept’, ‘be responsible’. Of course, it is generally taken for granted that seeking for the truth is an aspect of being good; and, sure enough, following the evidence where it leads is apt to involve a responsible decision - especially when one’s peers or paymasters have an interest in one’s failing to do so.

The arguments of Hume and Kant against rational theism are to be contested as due to an inadequate theory of knowledge. In accordance with a fully worked-out critical realism, one conceives and affirms an ‘unrestricted act of understanding’ (God) which understands all possible worlds, and wills the one which actually obtains; such a being must exist if the intelligibility of the world is to be adequately explained. Given the notorious fact of moral evil and human deficiency in general, one might have expected God to act in such a manner as to remedy the situation; attention to human history indicates that God has actually done so. However far rational self-consciousness is developed, the human emotional needs apt to give rise to myth remain; the remedy takes the form of an actual human history which provides humankind with the emotion-laden symbols of myth without its falsifications.

Lorenzen, Paul (1915-95)

Paul Lorenzen, German philosopher of mathematics and sciences, programmatically set about implementing mathematical constructivism in wider philosophical contexts. Trained as a mathematician, he spent the greater part of his teaching career at the University of Erlangen, Germany. Here he assembled what came to be known as the 'Erlangen school', which included Wilhelm Kamlah, Kuno Lorenz, Jürgen Mittelstraß, Peter Janich, Oswald Schwemmer and others. In its heyday, the school also influenced work at the universities of Konstanz and Marburg, and was one of the main alternatives to 'traditional' philosophies such as hermeneutics.

The school's interests embraced mathematical logic, the major thinkers of the idealist and hermeneutic traditions (though not Heidegger), and a high level of philological expertise in classical philosophy. Regrettably, though, its encyclopedic initiative has remained incomplete, and the school has largely disbanded in the face of increasing polarization between straight analytical philosophy and a tougher response by existing traditions. To some extent, Lorenzen's own express interest in left-wing political traditions became a liability in view of the sobriety and retrenchment that characterized the 1980s.

1 Lorenzen's constructivism

Lorenzen's work articulates concerns brought on by the fate of philosophy under National Socialism. He distrusted instrumentalist refusals to engage with foundational issues in epistemology, since this had (it appeared) contributed to the nationalism of the cultural sciences, the positivism of jurisprudence, and the racism of those philosophers of science who proclaimed such fantasies as 'Aryan physics'. Lorenzen's 'constructivism', by contrast, starts from the insistence that it is possible to establish a firm bridgehead in reality by a version of operationalism: we know what we have created, and to the extent that we repeatably create external things we are by that token entering reality. So while we may be unable to describe 'reality' *tout court*, we can say as much as we want about those parts that we can reproduce at will by means of effective procedures.

Lorenzen contends that all knowledge is derived from privileged practices and 'operations', that there is no knowledge that is not in some sense practical knowledge, and that it is precisely active intervention that constitutes our rational being in the world. There are two major steps in Lorenzen's arguments. The first is the determination of knowledge-constituting activities: where do deliberate human practice and intelligible reality coincide as perfectly as operationalist epistemology envisages? The second step extends this epistemological principle to issues in moral philosophy.

2 Counting and other operations

Traditionally, counting, as represented by the natural numbers and arithmetic, was the constructivists' favoured 'operation', as shown in Brouwer's contention that mathematics 'is more an activity than a doctrine'. Despite supplying the basis of the most refined structures the mind is capable of conceiving, counting is a practice common to all rational beings, and one whose practical effectiveness is vindicated by repeated application in all the concerns of human life. The philosophical challenge was to show that complex mathematical instruments such as analysis - or, failing that, equivalent substitutes for them - could be derived, 'constructively', from basic intuitive operations like counting. Non-constructive steps in the argument (such as the *tertium non datur*) had to be excluded, or interpreted in terms of some additional constructive principle. This is the area from which Lorenzen's own earlier work grew.

But counting is only a single, restricted 'operation'. In particular, it does not suffice to ground other branches of mathematics, such as geometry or mechanics, which require some account of spatial and temporal elements. To obtain these, Lorenzen turned to the work of Hugo Dingler (Dingler was an opponent of the Vienna Circle; discussion of his ideas can be found in early issues of *Erkenntnis*). Dingler had argued that a Euclidean geometry could be reconstructed by reference to certain intuitive practical activities. In particular, the production of plane surfaces was something for which lens grinders had an eminently effective procedure (they grind three objects together until one designated surface of each is exactly congruent with the designated surfaces of both others). Once plane surfaces have been effectively derived, other elements (straight lines, points) could be derived by further intuitive manipulation (a straight line is the intersection of two plane surfaces, a point is the intersection of

two straight lines). Just as constructivist mathematics rejected the use of non-constructive elements in justifying maths (because they interrupted the chain of derivation from assured reality), so also Dingler rejected non-Euclidean approaches because they could not be intuitively grounded (see Dingler 1987).

The attempt to provide 'operative' foundations for mechanics - and hence for physics - has been extended into chronometry and stochastics in the so-called 'protophysics' of Lorenzen's pupil Janich. The central feature of this broadened constructivism is the attempt to find procedures that are repeatable under contextual invariance. Counting has this effect: whether you count apples or sheep, the results of this procedure (natural numbers) have the same properties in either case. In principle at least, Dingler's lens-grinding procedure in every case produces something (a plane surface) with the same properties. Clearly, few procedures satisfy this requirement of contextual invariance. Baking depends for the properties of its results on 'contextual' elements such as the ingredients I use; running depends on where I start from; and so on. But to the extent that we can find procedures that are contextually invariant, we have discovered operations that *are generally constitutive of intelligible reality*.

The most satisfactory examples of such procedures are in the schemata by which we conceptualize reality. Counting, as we have seen, is one of those. Lorenzen made two attempts, however, to extend this into the philosophy of language (see Constructivism; Constructivism in mathematics; Operationalism).

3 Ortholanguage and dialogical logic

One attempt consisted in the development of a so-called 'ortholanguage' (with Oswald Schwemmer). This was based on an inversion of the 'classical' priority of syntax over semantics. Although the constructivist interpretation of counting as a general procedure already abandons the set-theoretic model of the universe, a general prioritization of semantics requires more. The ortholanguage attempted to supply this by specifying absolutely general *pragmatic* features of speech. In its details this project was not very successful and seems to have been abandoned (the basic semantic 'procedure' was giving orders, which does not entirely commend itself!). None the less it formed part of a wider project which produced the *Logical Propaedeutics* (1973), which became the Erlangen school's most widely influential text. It is best described as a constructivist introduction to philosophical logic.

Logical Propaedeutics, apart from setting out in general terms a derivation of the principles of rational communication from certain foundational pragmatic interests, provides an interpretation of the logical constants. This is perhaps the most interesting and enduring of Lorenzen's contributions. He calls it 'dialogical logic'. The classical approach to philosophical logic, Lorenzen argues, rests on metaphors derived from set theory. The assumption is that intelligible statements about the world are reducible to elementary propositions about whether objects are or are not elements of sets. A classical approach can then interpret the logical constants - or at least the connectives - in terms of these depictions of states of affairs. Wittgenstein's use of truth tables in the *Tractatus* is a celebrated example (see Wittgenstein, L.). (Lorenzen also calls this approach 'semantic'.) Unless the system is to be disengaged from ontology and treated instrumentally, however, problems with 'difficult' sets (non-finite sets, self-membership and so on) have to be faced. In particular, truth tables presuppose that the truth-values of all the elementary propositions are determinate. But this raises difficulties, for example, in the case of the universal quantifier, and is by no means as intuitive as its proponents claim.

Lorenzen's constructivism supplies an answer. The logical constants are now interpreted as strategies in two-person games. They indicate a certain procedure in an argument; and the truth-values of elementary propositions are then presented no longer as pre-existing states of affairs, but as matters which might (or might not) fall for determination in the course of the strategy pursued. It might be, for example, that dialogue partner *P* puts forward a conditional sentence, $p \rightarrow q$. While the truth table interprets this as a collection of fixed assertions about *p* and *q*, the dialogue interpretation says it is no more than an offer to negotiate in certain determinate ways. If, for example, the opponent *O* challenges with the statement '*p*', then, in order to make good the initial claim, *P* will affirm '*q*'. If *P* cannot do that, *O* will win. If, on the other hand, *O* challenges with '$\neg q$', *P* will have to affirm '$\neg p$'; and so on. For certain affirmations there is always a winning strategy, and such formulations correspond to the 'logical truths' or 'tautologies' of the classical interpretation.

The advantage of this becomes more obvious in the case of the quantifiers. A universal quantifier is now not to be interpreted as a statement about some actual (and possibly infinite) totality of states of affairs, but as an offer to

negotiate on the basis that the assertor challenges their opponent to find a counterexample - or, after a completed dialogue, that the challenge was made and not successfully taken up.

This idea has a precursor in Gentzen’s ‘natural deduction’, and to a degree it has a rival in similar ‘games’ devised by J. Hintikka (1983). The core of Lorenzen’s approach, however, is its strong constructivism, which is most evident in its insistence on the concrete temporality of the dialogue. As Lorenzen points out, much depends on the dialogical rules adopted for these exchanges, for they determine which statements are to be tautologies, and it is over the question of what is to be a tautology and what is not that, for example, constructivists and classical logicians part company. These rules relate largely to the number of times each participant may respond to statements by an opponent (by attacking affirmations or defending themselves against attacks). If these rules are completely liberalized, and each side may continue attacking and defending until they have covered everything, then central classical tautologies (*tertium non datur*, *reductio ad absurdum*) become universally defensible strategies. These are excluded once the rules are tightened, for example, by specifying that *P* - the person making the original declaration - may *attack* any statement made by *O*, but may only *defend* himself or herself against the last attack.

Of course, the problem now arises over how such rule-making decisions may themselves be justified ‘constructively’. Ideally, one would wish to do this by showing that the dialogue rules were intuitively more satisfactory than, say, the ontological insinuations of truth tables. This is not easy. Lorenzen seems to offer two responses. One assumes that the tighter rules are the intuitive ones. However, we need most of classical logic (including *reductio*) to be able to reason at all. We therefore have to enrich our original dialogical intuition with liberalization. In other words (interpreting this) we need tolerance in order to do science.

The other response does not really follow from the dialogical interpretation, but recurs to constructivism’s ontological conviction that future facts (or otherwise unavailable facts) are not facts and hence do not fit into truth tables. This justifies rules excluding *tertium non datur*, and vindicates dialogues as part of the dynamic by means of which human beings construct their own future facts (see Dialogical logic).

4 Conclusion

Lorenzen is a transcendental pragmatist: that is to say, he thinks that certain activities provide direct access to reality, and that the conditions of such activities are thereby in some sense transcendental conditions of knowledge in general. The problem lies in identifying these activities. Counting is one possibility, and has done useful service for classical intuitionism. It is limited, however; and other attempts to extend the range of foundational activities within physics (Dingler, operationalism generally) have not been entirely convincing. The most widely canvassed transcendental activity - by Apel, Habermas and others as well as by Lorenzen - is language itself. But, as Wittgenstein asked in the *Philosophical Investigations*, to what extent is ‘language’ a single activity? The various transcendental-pragmatic attempts to determine precisely what this activity is have usually led to suggestions that are unconvincing or trite or both. In particular, the recurring suggestion (in Lorenzen, Habermas and elsewhere) that speaking somehow presupposes tolerance and openness, and thus has a natural telos in good behaviour, seems ultimately specious.

Despite any reservations one may have about the system eventually generated by Lorenzen and his followers, their work combines deep scholarship with breadth of interest and a properly philosophical emphasis on the moral and political aspects of reason.

Losev, Aleksei Fëdorovich (1893-1988)

A leading Russian philosopher, religious thinker and classical scholar of the twentieth century, Losev made important contributions to the theory of language, myth and symbol, as well as to the understanding of ancient Greek thought and culture. He strongly resisted central aspects of modernization, in particular the spread of what he saw as 'bourgeois' and 'philistine' secularism, positivism, materialism, atheism, selfish individualism and 'machine civilization'.

A scholar of staggering erudition with a lifelong passion for the ancient world, especially the thought of Plato, Losev could be a fierce, sometimes abusive polemicist. His relation to the Soviet regime ranged from open defiance in the late 1920s (which led to prison and the gulag for almost three years) to at least pro forma *acceptance of certain key elements of Marxist ideology and philosophy in the period between 1953 and 1988.*

1 Philosophy of language, myth and symbol

Aleksei Fëdorovich Losev was born in Novocherkassk. While studying at that city's classical gymnasium, from which he graduated in 1911, he made his first acquaintance with the works of Plato and Vladimir Solov'ëv, both of whom were to remain at the centre of his intellectual interest for the rest of his long life. He graduated from Moscow University in 1915 in both philosophy and classics. Among his teachers were L.M. Lopatin, G.I. Chelpanov and G.G. Shpet. Boris Pasternak was a university classmate.

In 1914 the university authorities sent Losev to Berlin to do research in medieval philosophy in preparation for a university career in Russia. His stay was cut short by the outbreak of war, and he never again travelled outside Russia. In 1919 he was named a professor at the University of Nizhny Novgorod. From 1921 he taught the history of aesthetics at the Moscow Conservatory and then, with the rank of professor from 1923, taught a variety of subjects at various institutions of higher education. From 1942 until his death (in Moscow) he was a professor of classics at the Lenin Pedagogical Institute in Moscow. As a result of his trying experiences in the gulag in the early 1930s he was judged in 1947 to be clinically blind. His prodigious scholarly output during his final four decades (a lifetime total of some 400 scholarly works, including thirty monographs) was made possible by his second wife, A.A. Takho-Godi, a classicist and his former student, as well as by various polyglot secretaries.

When between 1927 and 1930 Losev was publishing his first eight, 'privately printed', volumes - what Khoruzhii has called his 'Octateuch' (*Vos'miknizhie*) - he used three techniques to confuse the Soviet censors: (1) misleading titles, especially for his 900-page *Ocherki antichnogo simvolizma i mifologii (Essays in Ancient Symbolism and Mythology)* (1930a), which in fact consists of an extended monograph on Plato's theory of ideas and shorter monographs on Plato's social philosophy and Aristotle's ethics and aesthetics; (2) a ponderous technical terminology with many Greek-based terms and a dense and difficult philosophical style - especially prominent in *Filosofiia imeni (The Philosophy of the Name)* (1927b); (3) careful avoidance of the words 'God' or 'Deity' in what are clearly theological discussions (again, most in evidence in Filosofiia imeni). It was not until his final book of the series, *Dialektika mifa (The Dialectic of Myth)* (1930b) that Losev ventured to use the word 'God' - which in fact occurs frequently in the final chapters of that work.

Losev is unique among Russian thinkers in combining close scholarship in several languages - including the translating of, and commenting on, key classical and medieval texts - with bold and sometimes fanciful speculation. His translations of works of Aristotle, Plotinus, Proclus, Sextus Empiricus and Nicholas of Cusa have been widely praised, as has the splendid four-volume translation of Plato (1968-72) that he co-edited with V.F. Asmus.

Although Losev's Russian Orthodox convictions can be read between the lines in several of his works published in the late 1920s, he managed to avoid public censure, except for one attack by A.M. Deborin in 1929. Perhaps partly as a result of this relative impunity, he was emboldened to make his criticisms of Soviet ideology and practice sharper and more explicit, and his religious views much more open, in two works published in 1930. In *Ocherki antichnogo simvolizma i mifologii* he declared that a proletarian state cannot permit the existence of free art or science; if it does, such science may begin to refute Darwin's theory. 'It is necessary to forbid the refutation of Darwin and to devote major resources to the refutation of Einstein' ([1930a: 822] 1993: 837). As he admitted to a

Western visitor in the 1960s, this was meant ironically; but the Soviet censors took it with deadly seriousness. And they were outraged by his claim that '''dialectical materialism'' is a scandalous absurdity, the total flaunting of all dialectic and a most typical abstract bourgeois metaphysics' (1930b: 147; 1994: 123).

The axe fell promptly, with denunciations in *Pravda* and *Izvestia*, and a diatribe delivered to the 16th Party Congress (1930) by L.M. Kaganovich. Losev was arrested in April 1930 and spent eighteen months in prison (four of them in solitary confinement) under interrogation. He was sentenced to ten years in the gulag, and his wife to five years, but both were released in 1933 on grounds of failing health. Losev was able to continue teaching but forbidden to publish (except one or two translations) until 1953, when, by joining in the universal praise of Stalin's pamphlet *Marxism and Problems of Linguistics*, he was able to resume publication, mainly in the field of classical philology.

In a letter of 30 January 1923 to his mentor and friend Fr. Pavel Florenskii, first published in 1990, Losev made clear that his interest in the philosophy of the name and the theory of language and symbolism generally, had theological roots. He sided with Florenskii in defending the controversial claims concerning *imiaslavie* ('glorification of the name [of God]'). His ontological model - widely applied in a variety of fields of thought and culture - is that of an essence (*sushchnost'*) and its 'energies' (*energii*). An 'energy' for Losev is not an Aristotelian *energeia*, in other words, the actualization (of a potentiality), but rather the 'manifestation' or 'expression' of an essence. As he wrote to Florenskii: 'The name of God is an energy of God's essence'. But, wishing to avoid the pantheism with which many defenders of *imiaslavie* had been charged, Losev added: 'The name of God is God Himself, but God Himself is not a name; God is above every name' (*Kontekst 1990*: 15). The theological implications of this position will be explored (briefly) in §3.

Losev envisages a hierarchy of essence-energy relations: *eidos* (Platonic Form) is manifested in myth, myth is manifested in symbol, and symbol is manifested in the person. Losev's dialectical phenomenology - as Zenkovsky aptly called it - is more dialectical than phenomenological, more indebted to Plato, Plotinus and Hegel than to Husserl. As both Zenkovsky and Khoruzhii (1994) have noted, Losev always enriched his Husserlian analysis of the structure of meanings with a very un-Husserlian intuition of inclusive 'total-unity' (*vseedinstvo*) inspired by Vladimir Solov'ëv. This is evident in his theory of dialectic and of language. Dialectic, he insists, 'is the sole method capable of grasping living reality as a [dynamic] whole'. And words - especially proper names - have a 'magical power'; they are instruments of 'living communion' of human beings with one another and with nature. A person for whom words were only sounds, devoid of meanings, would live in a 'deaf-and-dumb' universe, plunged in 'gloom and madness', an 'eternal prisoner of himself,… antisocial, uncommunicative, non-conciliar [*nesoboren*]' (1927b: 47; 1993: 642).

By 1927 Losev knew the first two volumes (1923, 1925) of Cassirer's seminal work, *The Philosophy of Symbolic Forms*. He found much that was congenial there, and was astonished to discover that Cassirer's view of myth and mythical time was very close to his own view of music and musical time. But he rejected Cassirer's sharp contrast between myth and science and asserted, against Cassirer, that myth has its own 'mythical truth' and 'mythical authenticity [*dostovernost'*]'. Furthermore, Losev insisted that mythical consciousness is an essential accompaniment of every culture, including our own, rather than an early, now superseded stage of cultural development, as many theorists of myth assumed (see Cassirer, E.).

2 Philosophy of history and critique of contemporary culture

Losev's views of European history exhibit an intriguing parallel with those of Konstantin Leont'ev. For both thinkers the high point of West European cultural and religious development came with the Middle Ages, permeated as it was by religious values and at the social level by *sobornost'* ('conciliarity' or 'organic spiritual togetherness'). (A significant difference is that Losev did not follow Leont'ev in looking to contemporary Greece and Turkey as models of effective resistance to the modernization that was sweeping Russia.) Since the Renaissance the cultural and spiritual movement of Europe has been retrograde: the Enlightenment, the French Revolution and the development of an influential bourgeoisie have resulted in social atomization, a self-centred individualism and the flattening and emptying of cultural and spiritual values in the movements of secularism, liberalism, technologism, positivism, atheism, a materialist ontology and an abstractly rationalistic, non-dialectical metaphysics - what Hegel had called *Verstandesmetaphysik*. When Zenkovsky said that Losev in his early works had developed a 'metaphysics of the name' he meant this as a compliment. Losev would have taken it as an insult,

insisting that Zenkovsky use the word ‘ontology’ if he meant simply a general theory of being.

Like Leont’ev, Losev was often abusive in his criticism of the various aspects of modernity just enumerated. Thus he spoke of the ‘nightmare of Kantian subjectivism and dualism’, branding Kant’s philosophy a ‘synthesis of a prison [the human self alone with its ‘hallucinations’] and nihilism’ (’Veshch’ i imia’ (1993: 860)). In praising Husserl for repudiating the naturalistic philosophy of his time, Losev went on to call it ‘a naturalistically-decadent [or ‘corrupt’ - *rastlennaia*] philosophy’ ([1930a] 1993). In 1962 he turned his abuse towards Husserl himself, accusing him of a ‘monstrous nihilism’ and of being a ’most dreadful illustration of the period of disintegration [*raspad*] of bourgeois philosophy’.

Losev’s repudiation of high technology is even more idiosyncratic than Leont’ev’s, and somewhat differently motivated. For Leont’ev trains, the telegraph and the telephone were destroying the independence of national and ethnic cultures; in Losev’s view machinery of every kind, along with electric light and power, are obtrusive, vulgar and destructive of high culture generally and spiritual values in particular. One can sympathize with his claim that ‘Gothic architecture is more beautiful than the latest barracks-like buildings’, and one can understand his statements that ‘Platonism is more beautiful than materialism’ and that the ‘ringing of [church] bells is more beautiful than the howling of automobiles’. But one is at a loss when Losev adds: ‘burning people at the stake is more beautiful than executing them by shooting’ (1930b). And his diatribe against electric light (which has a less hysterical prototype in a Berdiaev text of 1916) is simply baffling. For Losev electric light is ’dead, mechanical’, and exhibits the ’limitation and emptiness of Americanism and machine production’. It is ’lacking in Grace,… banal, and boring’. *Human* actions, like praying or making love, cannot be performed by electric light, but only inhuman and dehumanizing actions, such as examining a victim of torture or presenting a promissory note for collection. It is an act of ‘nihilism’ for a Russian Orthodox believer, Losev asserts, to replace a ‘living, trembling candle flame’ by the ‘trivial abstraction… of vulgar electric light’. He concludes: ‘Apartments in which there is no living flame - in a stove, in candles, or icon-lamps - are dreadful places’ (1930b: 63-4; 1994: 53-4).

There is a certain historical irony in the fact that Losev’s mentor and friend, Fr. Pavel Florenskii, no less devoutly Orthodox than Losev, was at this very time working conscientiously as a scientist and engineer to bring electricity to Soviet factories, offices and homes.

3 Philosophy of religion and philosophical theology

A key fact of Losev’s biography, not mentioned in §1, is directly relevant to his views on religion. For nearly six decades he had kept from the world, including his friends, associates and students, the fact that in 1929 he and his first wife had secretly taken monastic vows, that he was the monk Andronik. To his friends, even though many of them were aware that in his final two or three years Losev had taken to wearing a Russian Orthodox cross, this was a stunning revelation, first made public five years after his death at the Losev centennial conference in Moscow (October 1993). They might have been less stunned if they had paid closer attention to the several eloquent passages in *Dialektika mifa* celebrating the simple and devout lives of Russian Orthodox monks and nuns - their fasting, prayers and spiritual discipline.

Claims by such commentators as Nakhov (see ‘The Life and Thought of Aleksei Losev’ (1996)) that 1953-88 was Losev’s sincerely neo-Marxist period tend to be undercut by the fact that he was a Russian Orthodox monk throughout that period. This fact also focuses a clear new light on many of the discussions of religion in Losev’s works - both early and late - that had appeared on the surface to be either ambiguous or insufficiently explicit. And it throws a fresh, though not necessarily reassuring, light on Losev’s troubling statements (in his 1990 book on Vladimir Solov’ëv) about the ’ghastly historical satanism’ of such ‘amoral’ thinkers as Leont’ev, Rozanov and Nietzsche.

In his first published essay (1916) Losev had declared that ’Plato’s thought, which was… unilluminated by the Light of [Christian] Truth’, had nevertheless managed to attain ‘almost Christian revelations’, even though in Plato’s time the ‘world did not yet know the Word of God’. During the 1920s Losev spoke not of God (until the final chapters of *Dialektika mifa* in 1930) but of the ‘Primordial One’ (*Pervo-Edinoe*) or ‘Primordial Essence’ (*Pervo-Sushchnost’*). He reinterpreted the Platonic ideas as ‘radiant symbols’ which involve a ‘dialectical self-disclosure of the Primordial One’. His theology at this point is both apophatic (negative) and mystical: the Primordial Essence is knowable not in Itself but only through its ‘energies’. The name of that Essence ‘glows in

the immaculate splendour of sempiternal light… having overcome the darkness of the *meon* (non-being)'. For Losev the cosmos is a complex system of 'magical' and 'miraculous' words and meanings, all of which are grounded in the Primordial Essence, a Being - here Losev's language became quite biblical - from whose 'womb' there 'pours the inexhaustible stream of Its life and Its ever-new determinations' (1927b: 163; 1993: 732).

In his 1923 letter to Florenskii (see §1) Losev set out the last of his 'theses' concerning *imiaslavie* in these words:

> a person's energy is nothing more than the Divine energies as received by that person. In mystery and miracle God Himself, and He alone, acts authentically in His names, and the person becomes no more than a vessel of God's name.
>
> (*Kontekst 1990*: 17)

Losev would doubtless be willing to have these words stand as the valediction of the devout and learned, if sometimes irascible, monk Andronik.

GEORGE L. KLINE

List of works

Losev's main philosophical ideas are presented in eight works - ranging in length from fewer than 200 pages to more than 900 pages - privately printed between 1927 and 1930:

Losev, A. (1927a) *Antichnyi kosmos i sovremennaia nauka (The Ancient Cosmos and Contemporary Science)*, Moscow.(A close study of ancient Greek dialectic, including such principles as being and becoming and such categories as rest and motion, identity and difference, and space and time.)

Losev, A. (1927b) *Filosofiia imeni (The Philosophy of the Name)*, Moscow. (A phenomenological investigation, inspired by *imiaslavie* or onomatodoxy - the glorification of the name of God - of the objective and pre-objective structures of the name in their relation to *eidos*, *logos* and *meon*.)

Losev, A. (1927c) *Dialektika khudozhestvennoi formy (The Dialectic of Artistic Form)*, Moscow.(A highly theoretical discussion of such topics as the categorial structure of the *eidos*, essence and its 'energies', the antinomies of myth and meaning, and a typology of artistic forms.)

Losev, A. (1927d) *Muzyka kak predmet logiki (Music as a Subject of Logic)*, Moscow.(A phenomenology of pure or absolute music, a comparison of music and mathematics, and a close discussion of musical time, rhythm, melody, harmony and so on.)

Losev, A. (1928) *Dialektika chisla u Plotina (Plotinus' Dialectic of Number)*.(A Russian translation, with extensive commentary, of Plotinus' discussion of number in *Enneads* VI, 6.)

Losev, A. (1929) *Kritika platonizma u Aristotelia (Aristotle's Critique of Platonism)*.(A Russian translation, with detailed commentary, of Books 13 and 14 of Aristotle's *Metaphysics*.)

Losev, A. (1930a) *Ocherki antichnogo simvolizma i mifologii (Essays in Ancient Symbolism and Mythology)*, Moscow: Mysl'; 2nd edn 1993, with additional annotations.(Shorter essays on ancient symbolism and certain of the pre-Socratic philosophers, an extended monograph on Plato's theory of ideas, and shorter monographs on Aristotle's ethics and aesthetics and Plato's social philosophy.)

Losev, A. (1930b) *Dialektika mifa (The Dialectic of Myth)*, Moscow. This work is currently being translated into English by V. Marchenkov. A portion of this translation was published in *Symposion* 1, 1996. (Negative and positive definitions of myth; the 'dialectical' relation of contemporary mythology to science, religion and politics; and the distinction between 'relative' and 'absolute' mythology.)

Losev, A. (1963-94) *Istoriia antichnoi ėstetiki (A History of Ancient Aesthetics)*, Moscow: various publishers, 8 vols.(Losev's work in ancient thought and culture is perhaps best represented by this monumental work, the second volume of which (Moscow: Iskusstvo, 1969, 145-677) contains a magisterial study of Plato's views of art and aesthetics.)

Losev, A. (1990) *Vladimir Solov'ëv i ego vremia (Vladimir Solov'ëv and His Times)*, Moscow: Progress.(Losev's work in the history of Russian philosophy is best represented by this posthumously published volume.)The following posthumously published volumes, together with the reprint of 1930a, collect all of the eight volumes of 1927-30.

Losev, A. (1993) *Bytie. Imia. Kosmos (Existence. Name. Cosmos)*, Moscow: Mysl'.(Includes 1927a and 1927b, along with Losev's 1916 essay 'Eros u Platona' (Eros in Plato) and a previously unpublished article 'Veshch' i imia' (Thing and Name).)

Losev, A. (1994) *Mif. Chislo. Sushchnost' (Myth. Number. Essence)*, Moscow: Mysl'.(Includes 1928, 1929 and 1930b, and several previously unpublished texts.)

Losev, A. (1995) *Forma. Stil'. Vyrazhenie (Form. Style. Expression),* Moscow: Mysl'.(Includes 1927c and 1927d as well as several shorter works.)

Losev, A. (1996) *Mifologiia grekov i rimlian (The Mythology of the Greeks and Romans)*, Moscow: Mysl'. (Includes two extended works: *Antichnaia mifologiia v ee istoricheskom razvitii (Ancient Mythology in its Historical Development)*, first published in 1957, and a previously unpublished work, *Teogoniia i kosmogoniia (Theogony and Cosmogony).*)Several of Losev's shorter essays on language, symbolism and poetry are translated, by J. Hellie, in the special Losev issue of *Soviet Studies in Literature*, vol. 20 no. 2-3 (1984).

Lossky, Nicholas Onufrievich (1870-1965)

In 1922, the Russian neo-Leibnizian idealist Nicholas Onufrievich Lossky, one of his country's most distinguished professional philosophers, was banished from Russia along with more than a hundred other non-Marxist intellectuals whose influence the communist authorities feared. A prolific writer before his exile, Lossky continued to write and publish widely abroad, becoming not only the dean of the Russian émigré philosophical community but a thinker well known in Europe and the English-speaking world through many translations of his works.

The systematic structure and rationalistic tone of Lossky's philosophizing set him apart from most of his fellow Russian idealists, but like them he proceeded in his thinking from a strong conviction of the truth of Christianity; he wrote of his commitment to 'working out a system of metaphysics necessary for a Christian interpretation of the world' (1951: 266). He adhered to a radical form of theism according to which the created natural order has nothing in common ontologically with the divine order that created it.

Lossky is best known for a set of interrelated views in epistemology and metaphysics connected with what he considered his fundamental philosophical insight - the principle that 'everything is immanent in everything'. According to his doctrine of 'intuitivism' in epistemology, all cognition is intuitive; there is an 'epistemological co-ordination' of subject and object such that any object, whether sensory, intellectual or mystical, is immediately present in the mind of the knower. As the heir to a Leibnizian tradition in Russian metaphysics represented before him by Aleksei Kozlov and others, Lossky advanced a theory of 'hierarchical personalism' in which Leibniz's monads became interacting 'substantival agents' existing at various levels of development; the choices of these ideal beings generate the material world (henceLossky's term 'ideal realism' for his ontology) and their reconfigurations and reincarnations move the cosmic process towards the perfection of the Kingdom of God. In his 'ontological theory of values' Lossky affirms a metaphysical basis for absolute values and attributes all evil - including diseases and natural disasters - to the misuse of free will by substantival agents, both human and subhuman.

1 Life and neo-Leibnizian system

Lossky was born into a petty nobility family of Polish origin residing in the province of Vitebsk in western Russia. He received his philosophical education mainly at St Petersburg University (1891-8), studying under the noted Neo-Kantian Aleksandr Ivanovich Vvedenskii (1856-1925); subsequently (1901-3) Lossky also had periods of study in Germany with Wilhelm Windelband, Wilhelm Wundt and Georg Müller. He began teaching at St Petersburg University in 1900, and in 1916, by then a major figure in Russian philosophical circles, he was appointed to a chair of philosophy at the University.

A professed atheist and social radical in his youth, as an adult Lossky returned to his family's Russian Orthodox faith - a 'conversion' prompted in part by studying the thought of his religiously minded compatriots Tolstoi, Dostoevskii and Solov'ëv. At the time of the Russian revolution Lossky was active in the Constitutional Democratic Party. An opponent of the Bolsheviks both politically and philosophically, he was dismissed from his university position in 1921 and expelled from the country in November 1922.

Lossky's professorial career abroad was spent mostly in Czechoslovakia, where he taught at universities in Prague, Brno and Bratislava over the period 1922-45. In 1946 he moved to the United States, and in 1947 he was named professor at the St Vladimir Theological Seminary in New York. He retired from teaching in 1950. A frequent visitor to France in his later years, Lossky died near Paris on 24 January 1965.

The only Russian predecessor whose philosophical influence Lossky explicitly acknowledged was Aleksei Aleksandrovich Kozlov (1831-1901), a professor of philosophy at Kiev University from 1876 until illness forced him to retire in 1887, when he settled in St Petersburg. Thereafter developing his views in the private journal *Svoë slovo (A Personal Word)* (1888-98), Kozlov is credited with initiating a Leibnizian movement in Russian philosophy that was continued not only by Lossky but by Lev Mikhailovich Lopatin (1855-1920), who became professor of philosophy at Moscow University and president of the Moscow Psychological Society; by Kozlov's son, Sergei Alekseevich Askol'dov (1870-1945), who was a fellow student of Lossky's at St Petersburg University and is known particularly for his works in epistemology; and by a number of other less prominent thinkers.

The Russian Leibnizians all subscribed to a form of pluralistic idealism or personalism that was inspired by Leibniz's monadology (see Leibniz §§4-7). They saw in the monadology a conceptual framework for establishing the reality and independence of the individual person without abrogating the principle of the organic unity of the cosmic order. Even Leibniz's supposedly 'windowless' monads (see Leibniz, G.W. §4), these thinkers pointed out, already contained the stamp of the entire universe within each of them; the only thing needed for a fully interpenetrating, organic cosmos is to release the monads from their causal isolation and allow them to interact. This step was taken by Kozlov, who elaborated a metaphysical system called 'panpsychism', according to which individual conscious spirits are both substances and agents; Kozlov also, like Lossky after him, developed an intuitionistic epistemology. Lopatin, too, emphasized the agency of the spiritual entities that comprise reality, attributing to them the 'creative causality' from which all spatiotemporal causality is derived. A defender of free will, Lopatin was the first of this group of thinkers to devote close attention to questions of ethics. The Russian Leibnizians regarded the material world as a product of the activity of individual spirits and advanced theories of reincarnation based on Leibniz's concept of metamorphosis.

Lossky, the longest-lived and most productive member of the group, developed a worldview that was unusual in the history of Russian philosophy for its deliberately systematic character and its rationalistic elaboration. It was also an unusually comprehensive system, incorporating logic, philosophical psychology, epistemology, metaphysics, philosophy of religion, ethics and aesthetics - to each of which fields Lossky devoted at least one major book. The only traditional philosophical discipline that Lossky largely avoided was social and political philosophy - a surprising omission for a Russian philosopher.

In the sections that follow, Lossky's system is examined under the various labels that he himself employed to identify its principal elements.

2 Intuitivism

Lossky's intuitionist epistemology was sketched in his first book (1903) before its formal presentation in *Obosnovanie intuitivizma (The Intuitive Basis of Knowledge)* (1906). Its inspiration, however, dates from about 1898, as Lossky explains in an autobiographical passage in a subsequent work. He relates that, driving through St Petersburg in a cab one foggy autumn evening, sunk in solipsistic doubt,

> I was thinking that there are no sharp boundaries between things, when suddenly the thought flashed into my head: 'Everything is immanent in everything'. I sensed at once that the riddle was solved, that the elaboration of this idea would provide the answer to all the questions that disturbed me…. From that time on the idea of an all-pervading cosmic unity became my guiding thought. Developing it led me to *intuitivism* in epistemology, and to *the organic worldview* in metaphysics.
>
> (1938: 157; original emphases)

Lossky believed that this insight (dubbed the doctrine of 'absolute immanentism' by the eminent historian of Russian philosophy, V.V. Zenkovsky) pointed the way to overcoming what he called the 'epistemological individualism' of philosophers in the Cartesian tradition. These philosophers, according to Lossky, typically hold that because the only content of consciousness is subjective states, the knowing subject and the object of knowledge are separated from each other and can be connected only causally. Efforts to specify the causal relation invariably result in some form of subordination, he argues - subordination either of subject to object (materialism) or of object to subject (spiritualism). But if immanence is mutual, subject and object are immanent in each other and neither is subordinate, so that the correct conception is what Lossky calls the 'epistemological co-ordination' of subject and object. The cognized object itself is present in consciousness and is grasped as it is in itself (not as a copy, image or other representation). This immediate grasp of the object in itself is what Lossky means by 'intuition'.

Furthermore, the 'absolute' character of immanence entails that *all* objects of consciousness, of whatever sort, are immanent in consciousness, so that every object is directly 'given'; epistemologically, there is no root difference between sense perception and the spiritual contemplation of God. Hence Lossky affirms that all cognition is grounded in intuition, although he concedes that the establishment of *knowledge* on this ground requires further acts of attention, discrimination, and the like. In his book *Chuvstvennaia, intellektual'naia i misticheskaia intuitsiia (Sensory, Intellectual and Mystical Intuition)* (1938), Lossky identifies three varieties of intuition, which

he differentiates not epistemologically but according to the ontology of their objects: sensory intuition has as its object ‘real being’ - being with spatiotemporal existence; intellectual intuition is addressed to ‘ideal being’ - abstract entities conceived on the model of Platonic ideas; mystical intuition, finally, is intuition of ‘metalogical being’ - being that transcends the laws of identity, noncontradiction, and excluded middle, such as God. Lossky considered philosophical discourse a form of intellectual intuition, and thus held that rational, discursive thinking, rather than standing opposed to intuition, is one of its species.

The prominence of intuition in Lossky’s philosophy suggests comparisons with his French contemporary, Henri Bergson. Lossky knew Bergson’s work well and spoke highly of some of his views, especially the analysis of the physiology of perception and the theory of dream memory advanced in *Matter and Memory* (1896). At the same time, Lossky believed that there was a profound difference between his intuitionism and that of Bergson: for the latter, intuition discloses a conceptually unarticulated, irrational reality, whereas intellectual intuition as Lossky understood it displays the thoroughly rational and systematic structure of ideal being.

Zenkovsky criticizes Lossky’s statement of his theory of intuitivism on the grounds that it supposedly contains no actual intuitions; he finds in Lossky no ‘radiance of truth’, but only ‘ordinary theoretical *constructions* or *hypotheses*’ ([1948-50] 1953: 660-1; original emphases). But if we accept Lossky’s view of rational philosophical discourse as proceeding through the intuition of ideal being (‘intellectual intuition’), then ‘ordinary theoretical constructions’ do not exclude but rather presuppose the presence of intuitions. Moreover, Lossky’s initial consciousness of universal immanence (the sudden thought that ‘everything is immanent in everything’) seems a classic instance of the ‘radiance of truth’, on a par with the intuitive sense of ‘the oneness of being’ found in many mystical philosophies through the ages.

A more weighty criticism voiced by Zenkovsky has to do with Lossky’s apparent inability to explain the possibility of radical cognitive error. Lossky is willing to acknowledge no more than a partial deviation from truth in the epistemological process whereby intuition becomes knowledge; ‘like the other forms of intuition’, he writes, ‘mystical intuition cannot lead to ideas and concepts that are completely erroneous’ (1938: 198). In Lossky’s epistemology the fundamental coincidence of idea and reality is guaranteed by the mutual immanence of subject and object; indeed, if intuition is the ground of all cognition, and if in intuition the object *itself* is present in consciousness, it is difficult to understand how even a partial cognitive failure can occur. Yet surely, as Zenkovsky points out ([1948-50] 1953: 673), our ideas are at times radically erroneous. The reality of error requires us to assume a disjunction between subject and object that Lossky’s philosophy of ‘absolute immanentism’ cannot admit.

3 Theism

The ‘organic worldview’ to which Lossky subscribes in metaphysics is a view of the ‘world’ or cosmic order, but it does not describe the relation between God and that world. In Lossky’s metaphysics (best expounded in his book, *Mir kak organicheskoe tseloe (The World as an Organic Whole)* (1917)), the cosmic order within which organic unity prevails is a realm of being utterly different from the supernatural realm to which it owes its existence. Arguing that a world system cannot contain the ground of its own existence, Lossky contends that its ground can only be a Supracosmic Principle that transcends all systems. This is the realm of ‘metalogical being’ - a realm to which such cosmic categories as ‘reason’ and ‘person’ do not apply. Lossky holds, however, that in religious experience we recognize this Supracosmic Principle as God, as a Person, as Triune and the like, but he cautions that all such designations are based on ‘metalogical analogy’. Even the relation between the two realms requires analogical language: it can and should be called ‘creation out of nothing’, but ‘creation’ must be understood noncausally, because a causal relation requires some degree of ontological homogeneity, which does not exist in the relation between these two realms.

This dualism distinguished Lossky’s outlook from the monistic current, inspired by Vladimir Solov’ëv, that was more prevalent among Russian idealist philosophers of the early twentieth century (see Solov’ëv §§1-2, 5). Solov’ëv’s concept of ‘total-unity’ (*vseedinstvo*) incorporates Creator and created in a comprehensive organic whole with no ontological gulf between them. Whereas for this reason Solov’ëv and his followers are sometimes charged with pantheism, Lossky recommends his own view as the antithesis of pantheism, ‘the purest form of theism’ (1951: 265). Lossky does profess adherence to the doctrine of ‘Sophiology’ developed by Solov’ëv and other Russian idealists (see Solov’ëv §2), but he insists that Sophia is not an aspect or element of the Deity but is a

purely created spirit, standing at the head of all creation ('next to Christ as His closest co-worker') and receiving earthly incarnation in the form of the Virgin Mary.

4 Hierarchical personalism and ideal realism

In its treatment of the created order, Lossky's metaphysics marked the culmination of the neo-Leibnizian movement of ontological pluralism or personalism in late nineteenth- and early twentieth-century Russia. Agreeing with Kozlov that the myriad ontological units that comprise the cosmic order are not isolated or 'windowless', as Leibniz had conceived them, Lossky calls his interacting monads 'substantival agents'. He regards them as ideal (that is, non-spatiotemporal), active entities that are created by God as free agents and that ground the reality of every individual thing in the universe, from the smallest subatomic particle to complex objects at all levels of development. Even the simplest of these entities has the ability to 'choose' to subordinate itself to others to form a molecule, a cell or an organism. Indeed each substantival agent can rise to become eventually a human person, defined by Lossky as an ideal being capable of acknowledging absolute values and recognizing the duty to implement them; at still higher levels of development stand such 'persons' as tribes, states, heavenly bodies and the universe as a whole. On this basis, Lossky calls his outlook 'hierarchical personalism', with the qualification that lower, less developed substantival agents are merely potential rather than actual persons.

But what, then, of the spatiotemporal form assumed by these ideal agents in the material world? According to Lossky it is a by-product of their own free choices. To the extent that substantival agents, created by God, reject the Divine Principle and strive 'egoistically' to set themselves apart from the supraempirical Kingdom of God, their 'struggle' and 'acts of attraction and repulsion' produce the phenomenon of materiality. Thus space, time and matter are not God's creations. God creates only substantival agents, and he creates them radically free and indeterminate; hence he is not responsible for what each substantival agent makes of itself. Because on this view 'real' (spatiotemporal) being is a result of choices made by 'ideal' being in the form of substantival agents, Lossky calls his ontology 'ideal realism'.

It is not easy to square Lossky's conception of the indeterminate nature of substantival agents with the confidence he simultaneously exhibits in the progressive, teleological character of cosmic development, expressed in such statements as 'the ultimate universal victory of the good is guaranteed by the structure of the world' (1941: 79). Although on the one hand each substantival agent is said to forge its own destiny freely from the moment of its creation, on the other hand it would appear that the 'freedom' of the agent is limited by a direction (from the simple to the complex) and a goal (the production of human life) that are inherent in cosmic evolution. Thus Lossky wrote in one of his more imaginative passages:

> The human self is an agent that perhaps led the life of a proton billions of years ago. Then, gathering around itself a few electrons, it assumed the type of life of oxygen. Making its body still more complex, it then raised itself to the type of life of, say, a droplet of water. After that it made the transition to the type of life of a unicellular animal. After a series of reincarnations - or better, a series of metamorphoses, to use Leibniz's term - it became a human self.
>
> (1941: 33)

More tellingly, Lossky contended that through continued reincarnation 'all agents sooner or later overcome their selfishness' and enter into the Kingdom of God. He introduces the term 'normal [normative] evolution' for 'the line of development which leads straight to the threshold of the Kingdom of God' (1951: 264). To account for this benign tendency on the part of free agents, Lossky can only appeal to a principle of 'the inseparability of existence and value' that he says exists unconsciously as an ideal in every individual (1941: 51). But if individuals do harbour such an ideal, they are not fully indeterminate.

Questions of consistency aside, Lossky's doctrines of the voluntaristic character of evolution (even inorganic evolution) and of reincarnation as an evolutionary mechanism generated much controversy among his fellow Russian religious philosophers. Zenkovsky dismisses the doctrines as 'the most fantastic hypotheses' ([1948-50] 1953: 663).

5 The ontological theory of values

Lossky's conception (cited in §4) of a fully developed person as a substantival agent capable of acknowledging

absolute values presupposes that such values exist. In his ethical works (the most important of which are his 1931 and 1949 books), Lossky criticizes ethical relativism and elaborates what he calls his ‘ontological theory of values’, according to which absolute values are found in ‘the fullness of being’ that is God, as known through religious experience. In accordance with this conception, everything existing is valued from the point of view of its participation in and communion with the divine ‘fullness of being’: ‘Existence that brings us nearer to the absolute fullness of life is a positive value, and that which draws us away from it is a negative value’ (1951: 258).

Because spatiotemporal being results, as we have seen, from the wilful self-assertion of free substantival agents, the material world is truly a ‘fallen’ realm for Lossky; to call it an incarnation of evil would be redundant, for incarnation in itself is evil: ‘The whole [of] nature consists of entities which would have been members of the Kingdom of God had they not entered the path of egoism’ (1951: 262-3). The ’path of egoism’ or self-assertion is thus the source of all evil, natural as well as humanly produced. Unlike some other religious thinkers, who attribute humanly caused evil to the misuse of free will but have no comparable explanation of diseases and natural disasters such as earthquakes, Lossky ascribes the latter evils as well to immoral choices (presumably by subhuman agents such as molecules, cells and tectonic plates): all are ‘kinds of derivative evil necessarily connected with the relative separation of agents from one another and leading to ruptures and dissolution’ (1951: 262). Natural evils will be eliminated (along with humanly created evils) only when nature itself ceases to exist - as it indisputably will when all agents have attained the path of divine righteousness.

But if the explanation of natural evil presents Lossky with no special difficulty, on another level he is faced with the more general problem of explaining why there is evil at all, natural or human. He holds that evil at every stage of evolutionary complexity is produced by the will of substantival agents - specifically, by their will to elevate themselves above God. But what is there in the nature of these ideal beings as they come from the hands of God to induce them to make such bizarre and ultimately self-defeating choices - especially since, as we have seen, they come equipped with an inborn sense of ideal value? In the words of Natalie Duddington, Lossky’s first and principal English translator, ‘How could beings so admirably fitted by their Creator for a life of blissful intercommunion with Him suddenly conceive the impious thought of putting themselves in his place?’ (1968: 10). Duddington justifiably concludes that in Lossky’s account of the cosmic order as originally created by God there is nothing to explain the initial and continuing presence of evil.

Thus the problem of accounting for cognitive error, noted in Lossky’s epistemology in §2, is echoed in his ethics by the problem of accounting for moral error.

Lotze, Rudolph Hermann (1817-81)

Lotze was among the pre-eminent figures in German academic philosophy between the demise of Absolute Idealism and the rise of Neo-Kantianism proper. He sought to avoid two extremes: first, that of an idealism which seeks to deduce the world from a single, general principle; and, second, that of a realism which, by divorcing reality from the mind, splits the world into two utterly separate spheres. The search for knowledge should be tempered by a recognition of the results of natural science and sobered by the awareness that reality will, by necessity, always outstrip thought. Furthermore, our mental life cannot be reduced to purely intellectual functions: feelings and evaluations, for example, are also an integral part of human existence. While there can be no a priori deduction of a metaphysical system, a teleological interpretation, which elucidates the ultimate value of man and the world, must supplement purely naturalistic explanation. The universe has the significance of an unfolding plan, where things are subject to the general laws of order, expressing spiritual import. In this way, Lotze combined a kind of respect for the findings of scientific research with his own peculiar idealistic programme.

1 Philosophy of biology

Hermann Lotze was born in Bautzen and attended the Gymnasium at Zittau. At the University of Leipzig he studied medicine and philosophy. In 1844 he was nominated at Göttingen as the successor to Herbart in the chair of philosophy. Here he remained until the call to Berlin in 1881. His work after the ‘materialism controversy’ (from the convention at Göttingen in 1854) made clear his anti-naturalism and his affinities with the epistemological bent of early Neo-Kantianism (see Neo-Kantianism §2). A quasi-systematic philosopher, Lotze none the less eschewed the presumptions of German Idealism while preserving its ethical imperative.

As a student of Christian Hermann Weisse,Lotze fell under the sway of his teacher’s post-Hegelian view of idealism (so-called *Spätidealismus*). Yet as a medical scientist he came to reject key aspects of the idealist and Romantic philosophy of nature, most notably, its dependence upon the notion of ‘vital force’ (*Lebenskraft*) (see Naturphilosophie). After Kant there had quickly arisen an acceptance, within biological thought, of a special vital force, indicative of an organizing principle of organic bodies.Lotze presented a series of arguments designed to correct false applications of this concept. He reiterated Kant’s warning that the assumption of purposive organization could only be a regulative (not a constitutive) principle. As part of an organizing principle of merely subjective validity, the concept of vital force must not be hypostatized: that is, such force ought not to be treated as a material *cause* of organic phenomena.

Therefore, while inquiry must begin with the assumption of a purposive organization, no conclusion should be drawn which identifies vital force as an actual causal principle in the biological realm. On the other hand, this assumption does not imply that mechanistic explanation may be precluded. Teleology and mechanism are mutually compatible, not competing, investigative procedures. Lotze rejects the notion of a special force as superfluous for the scientific side of the investigation. Yet the formal constraint of ‘order’ or ‘purpose’ remains a necessary presupposition: mechanism should be understood as the way in which purpose realizes itself in our world.

As some concept of finality is required to fill the ‘metaphysical vacuum’ left by the intrusion of mechanistic procedures (not only in life science, but in the human sciences as well), an idealistic *Weltanschauung* is combined with a clear recognition of the power of scientific explanation. This requirement harks back to Fichte’s imperative to determine what *is* on the basis of what *ought* to be, but with an important difference: this ethical requirement, in Lotze’s hands, was translated into a new language of ‘values’. The terminology of ‘is’ and ‘ought’ is replaced by that of ‘existence’ and ‘meaning’: science may be allowed to determine what actually exists, but philosophy is required to expound what this existence means. These early convictions are retained in the mature expositions of Lotze’s thought, found in his *Mikrokosmus (Microcosmos)* (1858-64) and *System der Philosophie (System of Philosophy)*. Of the latter, which was intended as a three-volume work, only two volumes had been published at his death: *Logik (Logic)* (1874) and *Metaphysik (Metaphysics)* (1879).

2 Logic

The first book of the first volume of Lotze’s *System* begins with ‘pure logic’. He starts by affirming that our mental life - the ‘current of ideas’ - essentially involves ‘connection’: ideas appear in relations of succession or

simultaneity. But does this connection denote real coherence or mere coincidence? That is, are the associative connections found in the current of ideas sufficient for objective knowledge or indicative only of subjective error and illusion? Lotze concludes that coherence is distinguished from mere conjunction only by reference to a ground (or basis) for such coherence. And this investigation is the province of ‘thought’ proper.

Hence to logic, and not to psychology, belongs the discovery of the bases of justification. The dog can associate the raised stick (in the hand of its master) with pain, but only human thought can relate the identical matter in inferential terms, in virtue of logical consequence. The peculiar nature of thought thus lies in the supplement that it provides over and above the mere current of ideas: the addition of a justificatory ground (or rationale) for the connection. This, in turn, depends critically upon the capacity of thought to impose logical form. To provide for a firm structure of truth, it must arrange its building stones precisely. This foundation must, further, be of a form suitable for thought; so there must exist some process by which thought logically apprehends the sensory manifold.

Lotze believed that concept-formation belongs to thought proper and not to the psychological processes of abstraction or synthesis. This principle is to be established by a careful determination of the different stages involved in the refining of ideation into thought. The first step in the creation of logical building stones is the conversion of ‘impressions’ into ‘ideas’. This takes place by naming: in the process of designation one separates out objective ‘content’ from subjective ‘act’. The logical objectification (of what initially appears as subjective) proceeds through the categorization effected by the recognized parts of speech. In meaning (as opposed to mere venting) one calls upon the formal, grammatical categories of substantive, adjective or verb. These are mirrored in (or are shadows of) the logical categories of object, property and relation. While thought is not dependent upon language *per se*, it does depend upon some such inward articulation that respects these fixed logical categories; by contrast, the musical scale is an articulated structure, but not one which can support propositional thought.

Lotze proposed few formal innovations in logic. Among them was that found in his insistence that the coordination of part-concepts (*Merkmale*) in the intention of a given concept be expressed not in simple additive relations but rather in a functional representation. Instead of a simple equation, such as $S = a + b + c + \ldots$, a functional notation, such as $S = F(a, b, c, \ldots)$, indicates that the relations of dependence among the part-concepts must be determined according to a general rule or law. (The constant reference to rules and laws furnishes a leitmotiv of Lotze’s entire philosophical endeavour.)

3 Epistemology

Among Lotze’s best-known contributions to the theory of knowledge, found in the third book of his *Logic* (1874), is his reinterpretation of Platonism: the construal of metaphysical objectivity as epistemic validity. Lotze argued that Plato had been fundamentally misunderstood. In specifying that the Ideas were non-spatial, Plato had intended to imply that they were not ‘things’ at all. (Here ‘Idea’ invokes thought-*content*, not an *act* of ideation.) These contents are to be understood as having an existence completely different from the type of existence associated with objects or things. While physical objects can possess ‘being’ in the strict sense and events merely ‘occur’, such contents have ‘validity’. This implies a kind of epistemological realism: there are thoughts (or propositions) which are true or false and which are true or false independently of and antecedent to our judgment of them.

Such epistemic realism is sharply distinguished from any metaphysical variety. The latter view holds that these thought-contents must exist (or subsist) in some particular place. It may entail a false hypostatization that seems to follow from the correct emphasis we give to the independence of our thoughts from us. To assert the ‘objective significance’ of thought-contents is, hence, not to ascribe to them any sort of ‘real’ existence. Our apprehension of a thought seems to presuppose its existence in a preordained ‘place’; yet this can be nothing other than its setting within the inferential relations which hold between different thoughts and their meaningful components. As such, it is part of ‘a whole’: whatLotze calls the world of the ‘thinkable’. It is thus that the apprehension of a thought-content, as part of a larger system, may appear to be analogous to the perception of a physical object.

This picture affects the approach to epistemic justification that emerges in Lotze’s views on the validity of the Euclidean axioms. Even if our spatial perception depended upon some cognitive capacity such as ‘intuition’, Lotze argued, this fact alone could not account for our taking these axioms and their derivable theorems to constitute justified belief. Lotze tried to detach the concept of the a priori (as justificatory) from that of the innate (as genesis or source). Any sense in which one might speak of the innateness of Euclidean geometry only indicates causal or

psychological origin and is irrelevant to the question of justification. Instead, Lotze characterized a priori truths as those rooted in 'truths of universal validity, and thus prior to the particular instances in the sense of being rules by which they are determined' ([1874] 1887 2: 131). Yet this exhibition of truth must not be confused with the panlogicist attempt to discover truth by means of an a priori deduction. Rather, it is 'reduction' (or the regressive method) which makes possible the apprehension of the ultimate presuppositions of thought.

4 Metaphysics

Lotze also affirmed the centrality of 'law' in his conception of metaphysics. While metaphysics has a role in his system, it is a limited one: namely, to delimit not the thinkable, but the 'actual' - that is, what can be conceived of as actually existing or occurring without pain of contradiction. This constraint brings him to attack Herbart's theory of being in the first book of the *Metaphysics* (1879). The Herbartian view is indicated in the notion of 'pure being' as *Setzung*: that 'what we call the true Being should be found only in the pure "position", void of relation'. In fact, on this view, it is only because pure being lacks relations that existing things are able to enter into relations at all. Herbart concludes that reality is composed of something plural, simple and indestructible: what he called 'the Reals'. Since reality is compounded of substances that can suffer no change, and are hence immutable, the relations (into which things 'enter in') must be utterly external and accidental (see Herbart, J.F.).

Lotze's polemic stands in sharp opposition to this. He proceeds with an eye to the possible contradictions inherent in such an approach. On Lotze's account, relations 'between' things are impossible: therefore such relations must be internal. This relatedness is characteristic of being, yet not essentially so: what being *means* is something indefinable. Yet, the reality of being is ultimately exhausted by the reality of its relations. Being must be portrayed as part and parcel of a determinate and interconnected 'whole'. Hence, it is inconceivable that one might arrive at pure being through abstraction, by an attempt to negate all relations. This activity could only empty the concept of 'position' of all possible content.

Lotze also questions the view which makes the being of things (*qua* self-subsistent things) equivalent to a substantival notion of the Real. He points out that since 'real' can be used as an adjective, it may indicate a property of things. So the term 'real' cannot be used to characterize the being of things any more than the term 'position' can. Since what is real must be seen as part of an ordered system, its 'essence is only to be found in a law'. This points the way toward an interpretation of both the individual thing and the larger cosmos as systematic wholes, not as accidental juxtapositions of qualities or entities. All must be recognized as the ultimate workings of some Good, which orders and gives purpose to our reality.

WhileLotze formed no school, he influenced, most notably, W. Dilthey, R. Eucken, C. Stumpf, W. Windelband, G. Frege, E. Husserl, H. Rickert and B. Bauch. Abroad, his readers and admirers included Josiah Royce andF.H. Bradley. Lotze was a figure who marked the transition from the classical era of Goethe andHegel to a more scientifically informed philosophy. An original thinker in his own right - and despite his wide-ranging influence - todayLotze remains in relative obscurity.

Love

Love is usually understood to be a powerful emotion involving an intense attachment to an object and a high evaluation of it. On some understandings, however, love does not involve emotion at all, but only an active interest in the wellbeing of the object. On other accounts, love is essentially a relationship involving mutuality and reciprocity, rather than an emotion. Moreover, there are many varieties of love, including erotic/romantic love, friendly love, and love of humanity. Different cultures also recognize different types of love. Love has, as well, a complicated archaeology: because it has strong links with early experiences of attachment, it can exist in the personality at different levels of depth and articulateness, posing special problems for self-knowledge. It is mistake to try to give too unified an account of such a complex set of phenomena.

Love has been understood by many philosophers to be a source of great richness and energy in human life. But even those who praise its contribution have seen it as a potential threat to virtuous living. Philosophers in the Western tradition have therefore been preoccupied with proposing accounts of the reform or 'ascent' of love, in order to demonstrate that there are ways of retaining the energy and beauty of this passion while removing its bad consequences.

1 Love: emotion, relationship, action

Love is frequently understood to be a powerful emotion. It seems to involve both intense attachment to an object and a high appraisal of the value of the object. Often, though not always, the object is seen as something one needs in one's own life; for this reason love is often connected with projects of possession or incorporation, and with jealous emotions towards the object seen as separate and capable of frustrating the lover's needs. Spinoza (1677) argued that love involves an awareness of the object as promoting one's own wellbeing (see Spinoza, B. de §9). Since all particular objects are, in virtue of their separateness from the self, also capable of frustrating wellbeing, all love, he concluded, is essentially ambivalent, mixed with anger and even hate. One may, however, hold that love is an emotion or emotions while insisting that these emotions can be free from jealousy and possessive desire. Thus Plato, in the *Phaedrus*, imagines love as a powerful response to beauty and value that is linked closely, in good people, to reverence and awe; it thus respects the separateness of the object and seeks its good. These accounts describe different experiences, both of which can be real (as Plato, unlike Spinoza, recognized).

Love is not just an emotion: it can also be a type of relationship. Aristotle, in *Nicomachean Ethics*, insisted that (friendly) love always involves mutual awareness and mutual good will (see Friendship; Aristotle §25). While any account of love needs to make room for loves that are unrequited, or directed at objects which cannot reciprocate (infants, some animals) or do not do so clearly (God), Aristotle's insistence on interaction and mutuality provides an important ingredient for a normative account of many types of human love, both friendly and romantic/erotic. Indeed, the refusal to conceive of love in relational terms is a central defect in many instances of erotic love, in which the loved object is indeed treated as an object, to be possessed and immobilized. Although Proust believed that such projects were essential to erotic love, one might doubt this.

Some loves may not involve strong emotion at all. Kant (1797) insisted that 'pathological love' (love involving passive emotion) was inferior to 'practical love', an active attachment to the good of others, including emotions of respect and concern. Whether or not we agree, we should acknowledge that this active practical commitment is one type of love: the love of humanity, for example, may be best understood this way. The Greek Stoics believed that even erotic love could be reimagined in a way that rendered it compatible with the *apatheia*, emotionlessness, proper to the wise (see Stoicism §19). It would be an active enthusiasm about the good of the object, without the currents of agonizing passivity that usually characterize erotic attachment.

2 Types of love

English, like Latin, has only a single term for a large family of different experiences. Other languages, such as ancient Greek and modern Japanese, disambiguate the varieties from the start by the use of different terms. But even in English and Latin, we may distinguish different species of love. Erotic/romantic love is linked closely to sexual desire, while friendly love apparently is not. The love of parents for children and children for parents is frequently thought in the modern era to have an erotic dimension; but this was not the view of most earlier

cultures, nor is it likely to be true in cultures where well-off parents rarely saw their children. Ancient Greek culture thought of *eros* as sexual, concerned with possession, and potentially destructive; *philia*, which could obtain between either friends or relations, was seen as mutual and reciprocal, concerned with benefit, and a positive cultural force. Christian *agapē* is distinguished from both of these loves by its essentially selfless character; its paradigm is Christ's gift of his life for the redemption of sinful humanity (see Charity).

We may also categorize loves by their object-type. We love other people, and it is reasonable to expect that these loves will involve some reciprocity and mutuality. People's loves of animals may be very intense; they vary greatly in the type of reciprocity they offer. People also intensely love inanimate objects such as works of art and natural beauty. Such loves cannot be reciprocal. Love may also take as its object a moral abstraction, such as social justice, or the good of humanity. This type of love is especially well explained on the Stoic/Kantian model, as involving active commitment more than emotion.

The love of God or gods has been understood in many different ways. The Stoics thought that loving God was loving the rational purpose that animates the universe; such a love was best understood as a form of active thought, without any emotional receptivity. Spinoza's *amor intellectualis dei* follows this paradigm. Augustine, criticizing Stoic *apatheia*, insisted that a strongly emotional form of love, mingled with fear, guilt and mourning, is most appropriate to a Christian life (see Morality and emotions §5). Many Christian thinkers follow his lead. Jewish conceptions of the love of God tend to stress proper action, both ritual and ethical (see Ritual §§2-3). Modern religious thought continues these debates.

3 Cultural variation

Most societies contain many different types and conceptions of love. But cross-cultural variation also complicates analysis. Societies vary (a) in the behaviour they deem fitting in a relationship of love; thus modern American lovers behave publicly in ways that would have been unthinkable in nineteenth-century India. Variation is also present (b) in the norms societies teach concerning appropriate objects of love; thus fifth-century BC Athens taught young men that it was to be expected that they would have strong erotic desires for both males and females; many modern cultures do not convey this impression. Societies also vary (c) in their normative evaluations of different species of love itself - differing, for example, about whether erotic love is something noble or shameful, good or bad. All these variations can be expected to shape not only concepts but also the experience of love itself.

Most interestingly, societies also vary (d) in the precise taxonomy of types of love their language and form of life display and perpetuate. For example, ancient Greek *eros* is imagined as a terrible power that seizes the personality and causes it to fix on an object with overwhelming intensity. Its goal is taken to be the possession of the object. Medieval courtly love, by contrast, stresses the ideal purity and remoteness of its object and associates love with a tender and refined attention to that object. Those who nowadays have lost the beliefs and forms of life that grounded courtly love cannot experience exactly that passion.

Differences in taxonomy are often revealed and further shaped by differences in terminology: thus the fact that ancient Greeks distinguished *eros* from *philia* and Romans used only the single word *amor* probably shaped thought and experience to at least some extent, although Romans clearly did recognize different varieties of *amor*. (Similarly in the modern world, the fact that Japanese has several distinct words for what English calls 'love' probably reveals some real difference in experience, although these differences should not be overestimated.) In the modern world, understanding of cultural variation is complicated by inter-cultural contact and the translation of formative texts: thus the fact that Japanese *ai* is used to translate biblical *agapē* no doubt shapes the evolution of that concept as applied to experience.

4 Love and human development

People begin to have strong emotions before they can move or speak. A human infant's combination of cognitive maturity with physical helplessness gives rise to a complex and ambivalent emotional life, as it sees that the very objects it needs for comfort and survival are also separate and ungovernable. Spinoza's profound conjecture about the relationship between love and anger has by now received much clinical and experimental confirmation. One task of human development is to manage and even surmount this ambivalence, which will exist in many different forms in different lives, as love is powerfully shaped by the individual identity of the early objects of attachment.

The early experiences that shape the pattern of a person's loves are remembered imperfectly, if at all; even to put them into words is to change them. And yet it seems likely that they shadow one's later experiences. Proust plausibly suggested that when an adult embraces a lover, he or she is at the same time embracing the shadow of an earlier object. Thus Albertine is also the mother whose goodnight kiss the small boy so eagerly awaited. And yet it is difficult to grasp these aspects of oneself; even to the extent that one does, one alters the past by making it definite and articulate. So people's self-knowledge in love is likely to be very imperfect.

5 Love and human good: the ascent of love

Love is generally acknowledged to be a source of beauty and value in life. No philosopher, therefore, has proposed its complete removal. But it is also judged to involve various difficulties for a person aiming at a good and virtuous life. One concern is that love entails partiality: by focusing intensely on the value of a single object, one loses sight of the legitimate claims of other objects and goals (see Impartiality). A second concern is with excessive neediness: by allowing a single object to become central to one's life, lovers put themselves at the mercy of events that they cannot control, thus sacrificing their dignity and agency. Finally, partly because of this passivity, love is often linked with anger and revenge, whether against the loved object or a rival, or both. A society that wants to reduce anger and violence therefore may have reasons to discourage love.

Philosophers in the Western tradition have therefore been preoccupied with the project of constructing a reform or 'ascent' of love that would enable us to retain its mystery and beauty while purifying it of deforming excesses. For Diotima in Plato's *Symposium*, the ascent centrally involves the idea of an abstract object. Once one understands that the real object of one's love is not a body or even a whole person, but the beauty that is seated in that body or person, then one can begin a process of reform, compared to climbing a ladder, through which one eventually comes to love all the beauty in the universe, and, beyond that, to contemplate the deathless form of the beautiful itself in all its unity. In this way, lovers become invulnerable to life's vicissitudes: the object of their love will never betray or disappoint them.

Christian proponents of a 'ladder' of love tend to criticize the Platonist programme for its goal of personal self-sufficiency. Proper humility requires that one retain a continual awareness of one's incompleteness and neediness. Christian writers also attempt to retain the love of particular individuals as part of purified love.

Spinoza returned to a Platonic proposal for the contemplative reform of love: by focusing on the mind's freedom from external contingencies, one ultimately comes to love the deterministic structure of the entire universe, and one's mind is freed from the passivity and ambivalence that characterize human attachments.

A remarkable modern interpretation of the Platonic tradition can be found in Proust's *À la recherche du temps perdu (Remembrance of Things Past)* (1914-27), which asserts that each of a writer's loves is like a step in a ladder that leads him upwards to general forms, in which, alone, his intellect finds comfort and delight. By using one's past experiences of pain and vulnerability as raw material for a creative work of art, one surmounts vulnerability and achieves a kind of freedom from time and death.

None of these reformers likes real human beings very much. This tradition therefore gives rise to a counter-tradition that tries to restore human beings to a greater acceptance of their loves as they are, seeing the interest in ascent as itself a disease that needs curing. Much of this tradition lies outside philosophy. A salient example is Joyce's *Ulysses* (1922), which playfully turns Diotima's ladder upside down, indicating that it is only in the inconstant and flawed emotion of daily life that real love is to be found. By linking religious idealism with anti-Semitism and Bloom's love of the body with a general love of humanity, Joyce indicates, too, that the ascent tradition may be a cause of social hatreds, rather than their cure.

Löwenheim-Skolem theorems and nonstandard models

Sometimes we specify a structure by giving a description and counting anything that satisfies the description as just another model of it. But at other times we start from a conception we try to articulate, and then our articulation may fail to pin down what we had in mind. Sets seem to have had such a fate. For millennia sets lay fallow in logic, but when cultivated by mathematics in the nineteenth century, they seemed to bear both a foundation and a theory of the infinite. The paradoxes of set theory seemed to threaten this promise. With an eye to proving freedom from paradox, versions of set theory were articulated rigorously. But around 1920, Löwenheim and Skolem proved that no such formalized set theory can come out true only in the hugely infinite world it seemed to reveal, for if it is true in such a world, it will also be true in a world of the smallest infinite size. (Versions of this remain true even if we augment the standard expressive devices used to formalize set theory.) But then, Skolem inferred, we cannot articulate sets determinately enough for them to constitute a firm foundation for mathematics.

1 Background

To see how a model could fail to be standard, one first needs some idea of what a model is supposed to be. The basic distinction here is that between words and the world, signs and things. If the extension (denotation, reference) of each sign in a sentence or collection of sentences is held utterly fixed, and no re-interpretation is allowed at all, then what that sentence or collection commits us to should also be fixed. In that case there is little point in trying to distinguish various ways those sentences might come out true, that is, various models for them. If, in contrast, the extensions of none of the signs are in any way constrained, then just about anything could be gerrymandered into a way of making those sentences come out true. In this case too it seems unlikely that there will be interesting distinctions among the models. So the interest in models for a collection of sentences depends on holding the extensions for some but not all of the signs in those sentences fixed. (See Model theory.)

In modern algebra, a group is defined as a non-empty set *G* and a function $\circ$ such that:

(a) whenever *a*, *b* are in *G*, so is $a \circ b$;
(b) whenever a, b, c are in *G*, then $a \circ (b \circ c) = (a \circ b) \circ c$;
(c) there is a member *e* of *G* such that $a \circ e = e \circ a = a$ for each *a* in *G*; and
(d) for each *a* in *G* there is a member a^{-1} of *G* such that $a \circ a^{-1} = a^{-1} \circ a = e$.

The integers under addition constitute a group. The one-to-one correspondences between a set and itself also form a group under composition of those correspondences. Note that any model for the axioms is a group; there is no question of any groups being somehow standard, and others not. (On the other hand, because addition of integers commutes, that is, $a + b = b + a$, while composition of one-to-one correspondences need not, composition of correspondences illustrates groups in general better than addition of integers.)

If we put the second axiom of groups into the notation of quantification theory, we get

$$(\forall a, b, c)(a, b, c \in G \to a \circ (b \circ c) = (a \circ b) \circ c).$$

Any choice of a non-empty set for *G* and a binary function on *G* for $\circ$ is a candidate for a structure or interpretation making this axiom true. In this way, the extensions of the signs ‘*G*’ and ‘$\circ$’ are allowed a huge range of variation. But those of ‘$\forall$’, ‘$\in$’, ‘$\to$’ and ‘$=$’ are held fixed; they must be taken as universal quantification, membership, the conditional, and identity. This mixture of variation and constancy is part of what gives groups an interesting structure.

Modern algebra was a nineteenth-century development, and groups are an artefact of that growth. There was no favoured or intended group to begin with; it is instead the general group structure that proved to be of interest. So there is no distinction between standard and nonstandard models of the group axioms.

We think of groups as *given* by their axioms; they have no life prior to their characterization that would distinguish intended models of that description from unintended ones. But sets probably began life among us as extensions of predicates. On the one side there are predicates like ‘is a lion’. On the other, there are the lions. One way words and things link up is that all and only the lions are members of the extension of the predicate ‘is a lion’. We take the extension of a predicate as the collection, set or class of all and only the things of which that predicate is true.

Disguised as extensions sets led fairly inactive, boring lives in logic for ages.

But around the turn of the nineteenth century, reliance on geometric intuition led analysis, the theory growing out of differential and integral calculus, into paradox; intuition is not always trustworthy on infinitary processes. So a movement arose in nineteenth-century mathematics to replace geometry with arithmetic. We had learned in analytic geometry to individuate a point in the plane by an ordered pair of numbers, the point's abscissa and ordinate. Now we could rethink a literal curve passing (for example, continuously) through such points as some sort of arithmetical law, or even equation, relating the abscissas of such points to their ordinates. This rethinking of analysis is called its arithmetization.

The arithmetization of analysis focused attention on the kind of numbers used as coordinates of points on the plane. Nowadays we call these real numbers; they are the numbers used for lengths, temperatures and many other natural quantities, and given by decimals. Arithmetizing analysis calls for a clear view of the reals and their laws. To those with a taste for abstraction or essence, it even raises the question of what a real number is. Later on in the nineteenth century, Richard Dedekind showed how to answer this question by taking reals as (roughly) certain sets of rational numbers. (One can think of rationals as quotients of integers in lowest terms.) The details to one side, the idea is to rethink reals as certain constructions out of rationals using sets to do the constructing. Such constructions can be shown to satisfy the laws of reals needed to do analysis (see Dedekind, J.W.R.).

At that point we seem to be on to something. Reals are constructed from rationals using sets. It is a lot easier to construct rationals from integers (positive, negative and zero) using sets and to construct integers from natural numbers (non-negative whole numbers) using sets. Then Frege and Cantor seem independently to have got the idea of constructing natural numbers out of sets alone (at least that is how we in hindsight might put it). Sets seem to be becoming the basic stuff of mathematics, so if these sets are the same old extensions of logic, then perhaps, as Frege claimed, mathematics is reducible to logic (see Cantor, G.; Frege, G.).

The basic idea was to begin with the as-many-as relation. One set *A* has as many members as another set *B* precisely in case there is a binary relation *R* such that (1) for each $a \in A$ there is exactly one $b \in B$ such that *aRb*; (2) *R* matches different members of *A* with different members of *B*; and (3) for each $b \in B$ there is an $a \in A$ such that *aRb*. Beyond set-membership, only notions of logic (all, some, identity, and so on) are needed for this exposition of as-many-as. But with it, Cantor and Frege could take the number N_A of members of a set *A* as the set of all sets *B* with as many members as *A*, and a number as the number of members of some set (see Logicism).

But there is more. Mathematics had always looked to be about things like numbers, of which there are infinitely many, and triangles, of which there are infinitely many and in each of which there are infinitely many points. But mathematics lacked a good general account of the infinite *per se*. Dedekind provided one; a set is infinite precisely in case it has exactly as many members as one of its proper subsets (that is, a set included in but not exhausting the original set). Dedekind's account might have been only a curiosity had Cantor not proved that for each set, even infinite, there is a strictly larger set. At a single stroke, Cantor revealed a wealth of different infinite sizes, and thus a realm of transfinite arithmetic, which Hilbert called Cantor's paradise. Set theory looked to promise both a foundation for mathematics and a whole new mathematics of the infinite (see Set theory; Cantor's theorem; Continuum hypothesis).

But there were serpents in paradise. Most philosophers have seen Russell's paradox. Cantor's starts from a predicate like 'is a thing' which is true of everything. Every set would have to be a subset of *U*, the extension of this predicate, and so be no larger than *U*. But by Cantor's result cited in the previous paragraph, there is a set strictly larger than *U*. This contradiction together with Russell's and a third due to Burali-Forti constitute the paradoxes of set theory, and around the turn of the twentieth century some regarded these paradoxes as a crisis in the foundation of mathematics (see Paradoxes of set and property).

One response to this crisis was to formulate the mathematics at issue with unprecedented rigour. We would be utterly explicit about exactly which signs (that is, marks) may be written, how these marks may be concatenated, and how such strings may be manipulated. This idea of a formal system had been implicit in Frege, but it acquires a new prominence in Hilbert's programme for responding to the crisis in the foundation of mathematics. For once we have such a formal system we can ask whether anything with the shape of a contradiction can be cranked out by its rules of manipulation. Here we might prescind from all questions about how these marks might be

interpreted and focus instead only on which finite combinations of them the rules for their manipulation permit. This latter inquiry sounds like very elementary mathematics indeed. Hilbert's programme might look to show how to use only the most concrete and trustworthy mathematics, combinatorics, to prove the consistency of, and so to that extent legitimate trust in, the most basic (and so most powerful) set theory, at least as formalized (see Formal languages and systems; Hilbert's programme and formalism).

But now we have come back to a distinction between words and the world. On the one side, in the world, we have the sets. These are not just any old sets; they are to be a foundation for all of mathematics and to embody a new mathematics of the infinite. We have expectations of these sets; there are, for example, to be enormously many sets, many more than there are natural numbers or even real numbers. So much was promised by Cantor's theorem long before set theory got formalized, or even axiomatized. On the other side, in language, we have formalized set theory. To formalize it means to give its primitive marks and the rules for their manipulation just in terms of their shapes without a thought for how these marks might be assigned things in the world as extensions or interpretations. We want that purely formal presentation in hopes of as concrete and combinatorial a consistency proof for the system as possible. One might have other aims in formalizing, but Hilbert wanted a consistency proof as a *laissez-passer* back into Cantor's paradise. But having made this distinction between words and the world, one then can see the possibility of the words having an interpretation in the world quite different from what was intended.

2 One proof of the Löwenheim-Skolem theorem

In 1915 Leopold Löwenheim, a secondary school teacher, published a claim that a formula in the calculus of relatives that comes out true under an interpretation in an infinite domain also comes out true under an interpretation in a domain of the smallest infinite size. This size is that of the natural numbers, and domains of that size are called countably infinite. We might now describe the formulas in which Löwenheim was interested as those in which only the truth functional connectives and the quantifiers are interpreted uniformly across domains, that is, non-empty sets; the other signs, that is, constants, function letters and predicate letters, may be interpreted by any member of, or function or relation (of suitable polyadicity) on, any such domain. The consensus nowadays is that Löwenheim failed to prove his claim.

But after the First World War, the Norwegian logician Thoralf Skolem gave two rather different but equally correct proofs of Löwenheim's claim; this is the origin of the Löwenheim-Skolem theorem. Nowadays, one of these arguments is usually presented with a proof of the completeness of quantification theory (first-order logic). To show completeness, we start from a valid formula, that is, one true under all interpretations in all non-empty domains, and we must show that it has a proof by the rules of quantification theory. Equivalently by contraposition, we must show that a formula without such a proof fails in some interpretation. For this it suffices to show that any formula that yields no explicit contradiction by the rules is true in some interpretation. We can in fact show that the domain of such an interpretation need be no larger than countably infinite. But any formula true in some hugely infinite domain cannot yield a contradiction by the rules, and so by our result is true in an at most countably infinite domain.

Skolem not only proved Löwenheim's claim: he also strengthened it. For example, the claim holds not just for single formulas, but for countably infinite sets of formulas. Now remember our precisely formalized set theory. As standardly presented, this can be taken as a countably infinite set of sentences in which, over and above logic (which may be taken to include identity), there is only a single binary predicate (intended for the membership relation). Replace this binary predicate by a dyadic predicate letter allowed to be interpreted by any two-place relation on any non-empty domain. We get a set of formulas to which Skolem's strengthening of Löwenheim's result applies. Call this set of formulas the logical skeleton of set theory. It has lost its meat, the real extension of the predicate originally intended for the membership relation. It can be taken as the set of formulas that would be true were the predicate interpreted as intended, not just the theorems of some axiomatization of set theory. If set theory as standardly presented is, interpreted as intended, true, then because of Cantor's result on different infinite sizes, this set of formulas is true in a hugely infinite domain, namely, the world; and so by the Löwenheim-Skolem theorem, it is also true in an at most countably infinite domain. Indeed, since a countable model always has an isomorphic copy in the natural numbers, that countable model can be taken as one on the natural numbers. Hence the logical skeleton of set theory cannot come out true only when it is interpreted as intended in set theory. One

might begin to worry whether the laws of sets pin them down determinately enough for them to be a firm foundation for mathematics.

But raising this worry, as we have, with a spotlight on the logical skeleton of set theory suggests a way to assuage it. Surely parallel evolution could result in two very different animals whose skeletons are none the less indistinguishable. If so, an animal's skeleton need not individuate it. Similarly, the wealth of sets comes not from the logical form of (first-order) truths about membership, but rather from the nature of membership. For by the Löwenheim-Skolem theorem, the logical forms of the first-order truths of set theory come out true in a world vastly smaller than the real world of sets. So those forms alone fail to pin down the full nature of the membership relation, which is what makes the real world so big. That nature cannot be isolated just by the logical form of first order truths about it. Note in this connection that the proof of the Löwenheim-Skolem theorem sketched above makes no use of the huge model it supposes except to infer simple consistency; it constructs the small model from the merely consistent theory alone. Perhaps it is not surprising that with the meat thrown away, bones no longer carry its tang.

3 Another proof of the theorem and Skolem's paradox

But Skolem also proved the theorem in another way that makes much more intimate use of the huge original model. To get the gist, we need the idea of a Skolem function, which is another way of taking a quantifier in a model. A formula, perhaps with free variables, is in prenex form when all its truth functional connectives lie in the scopes of all its quantifiers. There are mechanical routines for finding prenex equivalents of formulas. Take prenex forms for each of the formulas in the logical skeleton *T* of set theory. Let these formulas be interpreted as intended in a huge domain *D* of sets on which *E* is the membership relation, the intended extension of the binary predicate letter that is the only extra-logical sign in *T*. (There may be a problem here. For model theory to be a theory, the domains of models should be objects we know how to handle. For that reason, they are usually required to be sets. But the standard response to paradoxes like Cantor's is nowadays to deny that there is a set of all sets. So if *D* is to be treated by the laws of all sets (as it is), then it had better not exhaust the sets, in which case *E* cannot be *the* membership relation.) Next we glance at orderings of *D*. A linear ordering of *D* is a two-place relation that arranges its elements as in a straight line; picture the relation of being-to-the-right-of. A well-ordering of *D* is a linear ordering *R* of *D* such that every non-empty subset of *D* has an *R*-least member, which then by linearity is unique. Being-to-the-right-of is not a well-ordering of the points on a line. But an equivalent of the axiom of choice of set theory says there is a well-ordering *R* of *D* (see Axiom of choice). Pick an arbitrary member *d* of *D* for don't-care cases. Let

$(\forall x)(\exists y)M(x,y,z)$

be one of our prenex forms, where *M* is a quantifier-free truth functional compound in which only *x*, *y* and *z* are variables. Skolem functions come from existential quantifiers in such prenexes. The existential quantifier binding *y* lies in the scope of one universal quantifier binding *x* and in a formula in which *z* occurs free. So the Skolem function for this quantifier is a two-place function *f* of the arguments *x* and *z*. For any members *x* and *z* of *D*, the value of *f* at *x* and *z* is the *R*-least member *a* of *D* such that $M(x,a,z)$ if there is any such *a* at all, but *d* otherwise (the don't-care case). Skolem functions are a little more complex in general, but that is the basic idea.

Take one prenex form for each formula in *T*. That is a countable infinity of forms, each of which has only finitely many existential quantifiers in its prenex. So there is only a countable infinity of Skolem functions. Pick any countable subset *A* of *D*, but toss *d* into it. Let A_0 be *A*, and for each natural number *n*, let A_{n+1} be A_n together with all the values of all the Skolem functions on members of A_n. We can show that for each *n*, A_n is countable, and thus that $D' = A_0 \cup A_1 \cup \ldots$ is also countable. D' is also closed under all Skolem functions; that is, if *f* is a *k*-adic Skolem function and $d_1, \ldots, d_k \in D'$, then $f(d_1, \ldots, d_k)$ is also in D'. This last is crucial; it comes from the fact that any prenex of any formula is finitely long, which comes from the fact that formulas are of finite size. Now let E' be *E* cut down to D'; that is, $aE'b$ if and only if aEb, and a, b are both in D'. The relation E' on the domain D' constitutes our new small model of *T*; it is called the Skolem hull of our huge old model.

A definition of satisfaction converts the extension E' of *T*'s only extra-logical sign into extensions in D' for each of its formulas. (See Tarski's definition of truth.) It is only for members of D' that there is much point in asking whether they do or do not belong to these extensions. Satisfaction also converts *E* into extensions in *D* for

formulas of *T*, and we can compare how these extensions treat objects from the overlap of their domains, namely D'. Let *F* be a formula of *T* in which the variables $x_1, \ldots, x_k$ occur free and let $d_1, \ldots, d_k$ be members of D'. Then we can show that $d_1, \ldots, d_k$ satisfy *F* as interpreted by *E* in *D* if and only if they satisfy it as interpreted by E' in D'. The two interpretations agree where both make sense. This includes all sentences of *T*, so the same sentences of *T* are true in both. All the truths of set theory were to hold in the big interpretation, so they hold in the smaller one, even the formalization of Cantor's theorem.

This time around E' has been carved directly out of *E*. All that has been pared away is whatever in *D* was unnecessary to make the formulas of *T* true when interpreted by *E*. But that turns out to be almost all of *D*. In particular, although a formula of *T* was intended under *E* to say that there are more than countably many things (in *D*), and though E' has enough of *E* for both to satisfy the same formulas in D', that formula intended to assert uncountability is true in D' even though D' is countable.

In 1922 Skolem wrote:

> *axiomatizing set theory leads to a relativity of set theoretic notions, and this relativity is inseparably bound up with every thoroughgoing axiomatization*….In order to obtain something absolutely non-denumerable, we would have to have either an absolutely non-denumerably infinite number of axioms or an axiom that could yield an absolutely non-denumerable number of first-order propositions. But this would in all cases lead to a circular introduction of the higher infinites; that is, on an axiomatic basis higher infinites exist only in a relative sense.
>
> (Skolem 1922)

These words are the origin of what has come to be called Skolem's paradox. It is pretty cut and dried what Russell's paradox is, but not Skolem's. Just what distinction between absoluteness and relativity did Skolem intend? Was it to be the same for notions as for existence? How does it line up with the countable/uncountable distinction? Do his results rule axiomatic set theory out as a foundation for mathematics?

These questions might lead us in many directions, but we have space only to gesture in one. When, then, might formulas capture, express or pin down a notion? One fairly evident idea is that they do so just in case all and only the models for those formulas exemplify the notion. In this way, the axioms for a group pin down the notion of a group because the groups are, not surprisingly, the models for those axioms. Perhaps formulas catch a notion absolutely if all and only the models for those formulas exemplify the notion. Then we note that uncountability is exemplified by some but not all models for *T*, so *T* does not capture uncountability absolutely but only, Skolem may have meant, at best relatively. (Maybe, but now there seem to be many things he might have meant.) Any first-order theory with uncountable models also has countable models, so no first-order theory guarantees that its models are countable, and thus satisfaction of a first-order theory does not guarantee the existence of an uncountable infinity. But satisfaction of the axioms of a group does guarantee the existence of a group. Some such contrast may be what Skolem meant by calling the existence of uncountable infinities relative.

4 One try at a solution to the paradox

Skolem seems to have had it in for set theory. But maybe the Löwenheim-Skolem theorem reveals not so much flaws in axiomatic set theory as limitations in the expressive powers of first-order logical notation. Skolem's words above hint that only a somehow question begging uncountable infinity of notations could guarantee uncountability in models of those notations. The circle is too faint. Is it vicious to use ink to describe ink, or to describe finitude in finitely many words? The hint seems suspect. Add to the notation a new quantifier '*Ux*' such that '$(Ux)Fx$' is true only in a domain with uncountably many members that satisfy *F*, and count as models only interpretations that verify '$(Ux)(x = x)$'. Would limiting ourselves to such models be any more circular than limiting ourselves to models without non-self-identical members?
